All the available practical and theoretical information on corrosion inhibitors used by industry for water and oil treatment has been consolidated in this comprehensive work. It collects data on specific problems and suggested remedies from the widely scattered literature in the field, and presents a complete and coherent review of current knowledge and practices.

200 pages, $12.50

DIGITAL COMPUTER PROGRAMS FOR PHYSICAL CHEMISTRY, Volumes I and II

By **Paul A. D. deMaine** and **Robert D. Seawright**

This work describes an integrated system of individual programs for the rapid and precise processing information in which the operator preselects limits for the experimental error. Only data describing the mathematical model to within the prescribed limits of experimental error are used to determine each parameter and its maximum permitted deviation. Both FORTRAN and AGOL 60 programs are given.

Volume I: Approximately 425 pages, $18.00
Volume II: In Preparation

SPECIALIZED STUDIES

International Series of Monographs on Nuclear Energy, Division IX: Chemical Engineering, Volume I

THE TECHNOLOGY OF THE TREATMENT OF URANIUM CONCENTRATES

By **N. P. Galkin, A. A. Maiorov,** and **U. D. Veryatin,** Atomizdat, Moscow. Translation edited by **Reginald W. Clarke,** A.E.R.E., Harwell

A complete and detailed account of uranium extraction technology from the ore concentrate stage to metal production. This unique translation from the Russian will prove useful to those concerned with the extraction of uranum ores of every kind.

A Pergamon Press Book 205 pages, $7.50

International Series of Monographs on Organic Chemistry, Volume 6:

ORGANOPHOSPHORUS MONOMERS AND POLYMERS

By **Y. L. Gefter,** Academy of Sciences of the U.S.S.R. Translated by **J. Burdon,** University of Birmingham

All the current information on polymers containing phosphorous has been collected in this one volume. It gives an account of the preparation of organophosphorus monomers, their polymerization, and the properties and uses of the polymers obtained.

A Pergamon Press Book 300 pages, $12.50

THE CHEMISTRY OF FLAVONOID COMPOUNDS

Edited by **T. A. Geissman,** University of California

This is the first complete summary of data on flavonoid compounds, including their recognition, isolation, characterization, identification, structure proof, interconversions, synthesis, stereochemistry, and biosynthesis. Methods of analysis and spectral properties are given in detail.

550 pages, $24.00

HYDROGEN BONDING: Papers Presented at the Symposium on Hydrogen Bonding, Held at Ljubljana Under the Auspices of the I.U.P.A.C.

Edited by **D. Hadzi,** Yugoslavia, with the cooperation of **H. W. Thompson,** F.R.S.

The results of a wide variety of experimental and theoretical work are available in this extensive and up-to-date treatment of the hydrogen bond. The experimental approaches discussed include X-ray and neutron diffraction, neuclear magnetic resonance, infrared and Raman spectroscopy, dielectric measurements, conductivity, and ultra-sound.

A Pergamon Press Book 450 pages, $17.50

ORGANOPHOSPHORUS POISONS, ANTICHOLINESTERASES AND RELATED COMPOUNDS

By **D. F. Heath,** M.R.C. Laboratories, Carshalton, Surrey

The fundamentals of the chemistry, biochemistry, and pharmacology of those organophosphorous compounds which are either themselves anticholinesterases or which are metabolized *in vivo* into anticholinesterases are carefully examined in this study.

A Pergamon Press Book 368 pages, $12.50

PROGRESS IN THE CHEMISTRY OF FATS AND OTHER LIPIDS, Volume 6

Edited by **R. T. Holman** and **W. O. Lundberg,** University of Minnesota, and **T. Malkin,** University of Bristol

Critical, up-to-the-minute surveys of special branches in the field are included in this collection of papers. They will be of interest not only to the specialist, but also to the chemist, biochemist, or medical scientist.

A Pergamon Press Book 364 pages, $15.00

CHEMISTRY OF ORGANIC FLUORINE COMPOUNDS

By **Milos Hudlicky,** Research Institute for Pharmacy and Biochemistry, Prague

This is a brief but complete picture of the present state of knowledge in the field, including all important discoveries in the methods of preparation and the reactions of organic fluorine compounds. All data necessary for conducting laboratory work is provided.

536 pages, $9.50

NATURAL ORGANIC MACROMOLECULES

By **Bruno Jirgensons,** Anderson Hospital and Tumor Institute, Texas Medical Center

A concise introduction to the chemistry of natural organic high polymers, this study offers methods for the isolation and determination of structure and configuration of macromolecules. It also provides surveys of the most important high polymers and their applications in the fields of biology and medicine.

A Pergamon Press Book 470 pages, $15.00

ORGANIC SULFUR COMPOUNDS, Volume I

Edited by **Norman Kharasch,** University of Southern California

Brief, authoritative, and well-documented articles concerning current research on every aspect of organic sulfur compounds are provided in this work. The first volume includes information on the physical properties of organic sulfur compounds, studies of reaction mechanisms, and progress in the synthesis and reactions of selected groups of compounds.

A Pergamon Press Book 633 pages, $20.00

INDEX TO REVIEWS, SYMPOSIA VOLUMES AND MONOGRAPHS IN ORGANIC CHEMISTRY, 1940-1960

Edited by **Norman Kharasch,** University of Southern California

Students, teachers, and research workers will find this a valuable guide to the experimental literature of organic chemistry. Approximately 7,000 major references are listed, including articles of theoretical, biological, pharmaceutical, and industrial interest.

A Pergamon Press Book 352 pages, $10.00

ELEMENTARY INFRARED SPECTROSCOPY

By **Clifton H. Meloan,** Kansas State University

A non-mathematical presentation for those with no previous background in spectroscopy, this book offers a concise analysis of the capabilities and limitations of infrared instrumentation. Following a brief history of the process, Professor Meloan describes the basic equipment, including sources, cells, monochromators, and detectors, and acquaints the reader with standard terminology.

192 pages, $8.95

CARBON: Proceedngs of the Fifth Conference (In two volumes)

Edited by **S. Mrozowski,** State University of New York at Buffalo, **P. L. Walker, Jr.,** The Pennsylvania State University, and **M. L. Studebaker,** Phillips Chemcal Company

These two volumes offer a complete survey of current work in the study of carbon in its many forms. The papers include studies of the physical and chemical properties of carbon and the scientific bases of manufacturing processes. They supply the results of research conducted in university, government, and industrial laboratories all over the world.

Pergamon Press Books

Volume I: 674 pages, $20.00
Volume II: 686 pages, $20.00

THE APPLICATION OF ORGANIC BASES IN ANALYTICAL CHEMISTRY

By **E. A. Ostroumov,** Academy of Sciences of the U.S.S.R.

The author of this work has collected a systematic series of studies on the application of organic compounds in the analytical chemistry of inorganic substances. Accurate and rapid methods for the separation and determination of a number of elements have been developed, involving the use of organic bases, pyridine, alpha-picoline, and hexamethylenetetratramine.

176 pages, $8.50

International Series of Monographs on Nuclear Energy, Division X: Chemical Engineering, Volume 2

ENRICHED URANIUM PROCESSING

By **F. S. Patton, J. M. Googin,** and **W. L. Griffith,** Oak Ridge, Tennessee

This comprehensive treatment covers the processing of U235-enriched uranium from the initial product of the isotope-separation plant to forms ready for final use. The book reviews chemical and metallurgical operations, as well as design, safety, economic, and waste recovery factors.

A Pergamon Press Book 282 pages, $7.50

International Series on Aeronautics and Astronautics, Division III: Propulsion Systems Including Fuels, Volume 1

CHEMISTRY PROBLEMS IN JET PROPULSION

In this book, the emphasis varies between qualitative surveys of basic principles and more detailed discussions of selected topics in combustion chemistry. The chapters on atomic and molecular structure provide a sensible appreciation of modern concepts derived from the application of wave mechanics. Combustion thermodynamics and chemical reactions in flow systems are also considered in detail.

A Pergamon Press Book 394 pages, $12.50

IRON ORE REDUCTION

By **R. R. Rogers,** Department of Mines and Technical Services, Ottawa

The Fundamentals of iron ore reduction are reviewed in this volume, including material on the most significant processes by means of which iron ore is currently being reduced on an industrial, pilot plant, or laboratory scale. Never before has the field been covered so thoroughly.

A Pergamon Press Book 340 pages, $12.50

DICTIONARY OF CHEMISTRY AND CHEMICAL TECHNOLOGY (English/German/Polish/Russian)

English Editors: **Professor H. Stephen** and **Dr. T. Stephen,** Oxford

In 724 pages, this dictionary lists some 12,000 English terms arranged in alphabetical order. Equivalent terms in each of the other three languages are shown alongside and numbered consecutively. German, Polish, and Russian alphabetical indexes conclude the dictionary.

A Pergamon Press Book 724 pages, $30.00

HANDBOOK OF MAGNESIUM ORGANIC-COMPOUNDS (Three volumes)

By **S. T. Yoffe** and **A. N. Nesmeyanov,** Academy of Sciences of the U.S.S.R.

The vast range of investigations on the magnesium alkyl and aryl halides is now assembled in this unique compilation. All the chemical reactions involving magnesium organic compounds which were published and abstracted between 1899 and 1948, together with work described in Russian papers not covered by abstracting journals, are here collected and systematized. Full references to the original literature and to the abstracts are included.

Pergamon Press Books 2020 pages, $72.00

A Wide Selection of New Textbooks

LABORATORY EXPERIMENTS IN ORGANIC CHEMISTRY, Fifth Edition

By **Roger Adams**, University of Illinois, and **John R. Johnson** and **Charles F. Wilcox, Jr.**, Cornell University

Beginning students of organic chemistry will find this a particularly helpful manual. It carefully establishes the relation between the theories taught in the lecture room and the laboratory exercises that illustrate them. The new edition has been extensively revised and greatly expanded. Even the format of the book and the type style have been altered to produce a larger page that is more legible. In many cases, variations of experiments have been included to emphasize that they are merely sample applications of a general reaction. For the further assistance of students, a convenient procedure for recording results, a guide to the strength of reagents, and the probable length of time required for each experiment have been included.

560 pages, $7.95

ORGANIC CHEMISTRY

By **F. G. Bordwell**, Northwestern University

This new text combines a consistently experimental approach with thoroughness and economy of presentation to provide an excellent introduction to the theories and practices of organic chemistry. An organization on the dual basis of structure and mechanism and the interweaving and sampling of less fundamental subject matter permits the book an unusual depth of coverage. At the same time, a cumulative expansion of the basic principles outlined in the first fourteen chapters reinforces the student's understanding of the properties of the important functional classes of organic compounds and provides an increasingly profound insight into each topic. The steps in the experimental determination of organic structures are clearly defined, and there is full instruction in the experimental use of spectra.

920 pages, $11.00

CHEMICAL ENGINEERING
Volume I: Fluid Flow, Heat Transfer, and Mass Transfer
Volume II: Unit Operations

By **J. M. Coulson**, King's College, Newcastle-on-Tyne, and **J. F. Richardson**, Imperial College of Science and Technology, London

This important work demonstrates that the processes of momentum, heat, and mass transfer are the underlying mechanisms of many chemical engineering operations. It considers chemical engineering in terms of the fundamental mechanisms involved, rather than as a series of isolated unit operations. Volume I deals with the laws of motions of fluids, generally, with particular attention to the calculation of the fall in pressure in pipes and the measurement of flow rates for both compressible and incompressible fluids. The general principles of heat transfer are also given, and the design of heat exchanges is discussed. Volume II covers the various unit operations of chemical engineering from a fundamental viewpoint, giving, in each case, the general principles of the operation of the equipment.

Volume I: 370 pages, $7.50
Volume II: 592 pages, $9.00

International Series of Monographs on Inorganic Chemistry, Volume 3:
AN INTRODUCTION TO CO-ORDINATION CHEMISTRY

By **D. P. Graddon**, University of New South Wales

Dr. Graddon's authoritative volume will be welcomed by those desiring a thorough and rigorous introduction to co-ordination chemistry. He supplies an interesting historical survey of the subject, dating from the earliest recorded co-ordination compound, Prussian Blue, obtained by the color maker Diesbach during the eighteenth century, to present day research findings. His subsequent discussions of the fundamentals and applications of co-ordination chemistry reflect the latest advances in theory and practice. A bibliography is included as a guide to further study.

A Pergamon Press Book 118 pages, $4.00

QUANTITATIVE CHEMICAL ANALYSIS, Twelfth Edition

By **Leicester F. Hamilton** and **Stephen G. Simpson**, Massachusetts Institute of Technology

The new edition of this highly successful text has been revised and expanded to incorporate new material on coprecipitation, ion-exchange, electrode potentials, electrolysis, acids, bases, and salts. In recognition of the growing number of colleges that offer quantitative analysis as a sequal to a course in organic chemistry, the authors have provided a new body of illustrative material. They include determinations that show how analytical techniques can be applied to the determination of organic functional groups such as the hydroxyl, phenol, nitro, and amino groups. Many problems have been reworded for greater clarity or conciseness, and all answers have been combined to form a separate section of the book. *Forthcoming*

International Series of Monographs on Organic Chemistry, Volume 5:
APPLICATIONS OF NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY IN ORGANIC CHEMISTRY

By **L. M. Jackman**, Imperial College of Science and Technology, London

This book develops the theory of nuclear resonance non-mathematically, in a presentation specifically designed to meet the needs of the organic chemist. Considerable space is devoted to correlated data and empirical theories which constitute the basis of the application of nuclear magnetic resonance spectroscopy to organic chemistry. This is the first book to give really precise correlations between chemical shifts and molecular structure.

A Pergamon Press Book 134 pages, $5.50

A SHORT TEXTBOOK OF COLLOID CHEMISTRY

By **B. Jirgensons**, Anderson Hospital and Tumor Institute, Texas Medical Center, and **M. E. Straumanis**, University of Missouri

The emphasis of this thorough introduction is on basic facts, established empirical and theoretical relationships, and practical applications. All types of inorganic and organic colloids are considered, including emulsions, foams, and aerosols, with attention to the effect of particle size and shape on the properties of the systems. The discussions reflect the most recent technological advances in viscometry and molecular weight determination of high polymers, denaturation of proteins, electron microscopy of colloids, and X-ray diffraction of gels and fibres. All experimental procedures are described in detail, stressing the methods that are currently in use in industrial and clinical laboratories.

500 pages, $10.75

REACTION KINETICS
Volume I: Homogeneous Gas Reactions
Volume II: Reactions in Solution

By **Keith J. Laidler**, University of Ottawa

Although suitable for use as an introductory text, these two volumes provide an unusually thorough treatment of chemical kinetics and the principles and mechanisms of reactions in solution. Volume I covers basic theory, molecular kinetics, and elementary and complex gas reactions. It includes valuable appendices on correlation and the method of least squares, and on numerical values. Volume II describes ion and dipole reactions, substituent effects, homogeneous catalysis, organic substitution reactions, and related topics. The extensive bibliographies provide up-to-the-minute source references.

Pergamon Press Books
(Commonwealth Library)

Volume I: 232 pages, paper, $3.75
Volume II: 136 pages, paper, $2.95

PHYSICAL CHEMISTRY

By **E. A. Moelwyn-Hughes**, University of Cambridge

This carefully planned and lucidly written survey of physical chemistry is both a thorough introductory text and a valuable reference work. It is based upon the latest theories, and includes both experimental and theoretical discussions of kinetic theory, quantum theory, and chemical thermodynamics. Separate chapters are devoted to intermolecular forces, partition functions, crystals, gases, metals, liquids, solutions, ions, and interfaces.

A Pergamon Press Book 1340 pages, $17.50

A PRACTICAL COURSE IN POLYMER CHEMISTRY

By **S. H. Pinner**, Essex

The experiments in this volume provide working experience for those interested in the synthesis and analysis of polymers. In addition to its value as a text, the book will prove useful to academic and industrial research workers beginning an investigation in the field of polymers. Research workers with rubber, fibres, and surface coatings will also profit from the discussions. The appendices to the book are entirely new and of special interest to more experienced polymer scientists, particularly those concerned with the determination of molecular weight by osmomery and viscometry.

A Pergamon Press Book 156 pages, $4.50

LABORATORY PRACTICE OF ORGANIC CHEMISTRY, Fourth Edition

By **G. Ross Robertson** and **Thomas J. Jacobs**, University of California at Los Angeles

The distinctive feature of this manual is its extensive treatment of the principles underlying laboratory manipulations. The new edition features an expanded and modernized discussion of general laboratory technique plus additions, deletions, and improvements in all experiments. There are new examples of elementary qualitative analysis, and the authors have expanded the selection of "Special Experiments," suitable for students who have acquired a firm grasp of the fundamentals.

391 pages, $5.75

EXPERIMENTS IN PHYSICAL CHEMISTRY

By **J. M. Wilson, R. J. Newcombe, A. R. Denaro**, and **R. M. W. Rickett**, College of Technology, Liverpool

Decidedly modern in its treatment and approach, this text offers complete coverage of pertinent theory and supplies a sound background for laboratory practice. The first two sections contain formal experiments covering the whole field of physical chemistry. The third section includes investigations on the order of minor research problems. Many of the experiments described involve instrumental techniques such as gas chromatography.

Announcing: An Important Interdisciplinary Series of Pergamon Press Books

THE INTERNATIONAL ENCYCLOPEDIA OF PHYSICAL CHEMISTRY AND CHEMICAL PHYSICS

Editors in Chief: **E. A. Guggenheim**, F.R.S., Reading; **J. E. Mayer**, La Jolla, California; and **F. C. Tompkins**, Imperial College, London.
Chairman of the Editorial Advisory Group: **Robert Maxwell**, Publisher at Pergamon Press

The International Encyclopedia of Physical Chemistry and Chemical Physics is to be an authoritative and comprehensive presentation of the domain of knowledge which lies between and overlaps chemistry and physics. The Editors-in-Chief have arranged the subjects into twenty-two topics. These groups were chosen to establish continuity and coherence within the Encyclopedia and to make the relation of each volume to the others apparent. Each volume is restricted to about 200 pages and may be used separately, without reference to other books in the series. Between 50 and 100 volumes are now planned.

Already published:

Topic 1, Volume 3
SYMMETRY: An Introduction to Group Theory and its Applications
By **R. McWeeny**, University of Keele, Staffordshire

This book offers a comprehensive and clearly written account of group theory and its uses. Emphasis is placed upon the finite groups which describe the symmetry of regular polyhedra and repeating patterns. Later chapters include many worked examples from molecular vibration theory and from atomic and quantum mechanics.

180 pages, $7.50

Topic 1, Volume 4
MATRICES AND TENSORS
By **G. C. Hall**, University of Nottingham

A survey of the theory of vectors, linear equations, matrices, and tensors is provided in his volume. It represents a link between introductory books on the subject and treatises written for expert mathematicians. An extensive bibliography is included.

116 pages, $6.50

Topic 6, Volume 1
APPLICATION OF NEUTRON DIFFRACTION IN CHEMISTRY
By **G. E. Bacon**, Metallurgy Division, A.E.R.E., Harwell

A thorough study of neutron crystallography, this book pays particular attention to the study of molecular structure, hydrogen bonds, and thermal motion through the determination of the position of hydrogen atoms. It will prove exceptionally valuable to chemists and crystallographers.

130 pages, $5.50

Topic 10, Volume 1
LATTICE THEORIES OF THE LIQUID STATE
By **J. A. Barker**, Division of Physical Chemistry, C.S.I.R.O., Melbourne

The relations between the molecular structure of liquids, the nature of the forces between the molecules, and the macroscopic properties of liquids are discussed in this thorough study. Detailed comparisons with experiments are made, the shortcomings of existing theories are demonstrated, and possible avenues for future research are suggested.

133 pages, $8.50

Topic 10, Volume 2
THE PERFECT GAS
By **J. S. Rowlinson**, Imperial College of Science and Technology, London

A concise account of perfect gases and gas mixtures is provided in this valuable study. Starting with the basic thermodynamics of a perfect gas, the book then describes experimental measurement of the properties of gases and the calculation of the thermodynamic properties of a perfect gas by the methods of statistical mechanics. It will prove an informative and practical reference work as well as an excellent introduction to the subject.

150 pages, $5.50

Topic 11, Volume 1
ELEMENTS OF THE KINETIC THEORY OF GASES
By **E. A. Gugghenheim**, F.R.S., Reading

This volume provides an elementary description of the most important features of the kinetic theory of gases. It should prove particularly useful to physical chemists and chemical physicists who lack the mathematical background demanded by more advanced treatments.

92 pages, $3.00

A Unique Set of Volumes that Will Prove Invaluable to Those Engaged in Interdisciplinary Research

ENCYCLOPAEDIC DICTIONARY OF PHYSICS
Editor-in-Chief: **J. Thewlis**, U.K.A.E.A., Harwell

International Edition. Prepared by 3609 distinguished physicists, chemical engineers, and mathematicians from every nation now making significant contributions to physical science.

After years of preparation, one of the monumental accomplishments of scientific publishing is now completed. Exhaustive, eminently authoritative, and entirely new, the *Encyclopaedic Dictionary of Physics* will prove indispensable to scientists, engineers, and teachers, as well as staff personnel in technical, research, industrial, and design organizations. Each article is written in a clear and direct manner by a noted specialist who is well acquainted with research and with literature on the subject, both past and present. Profusely illustrated throughout, the work includes approximately 6000 drawings, photographs, charts, diagrams, graphs, and tables. At the end of most articles there is an excellent, up-to-date bibliography. The set of seven volumes is now available.

In Addition—

Each purchaser of a set of the *Encyclopaedic Dictionary of Physics* will receive two valuable supplementary volumes *at no additional cost.*

Volume 8: SUBJECT AND AUTHOR INDEX
Arranged in strict alphabetical order, the index supplies all reasonable variations of the 10,000 or more terms listed in the seven volumes of the *Dictionary*, as well as showing where several thousands of topics are dealt with that do not form the topics of separate articles. There are 50,000 entries that will enable the reader to locate a particular topic at once, in any one of several different word orders.

Available in October

Volume 9: TRANSLATING GLOSSARY OF PHYSICS TERMS
The glossary will contain some 15,000 terms in each of the following languages: English, French, German, Russian, Spanish, and Japanese. All of these terms are related to the *Dictionary* itself. The first for languages represent all of the terms included in the *Dictionary of Nuclear Physics and Technology*, edited by Ralph Sube, in addition to its basic entries.

Available in December

Each of these two volumes will be shipped to owners of the *Encyclopaedic Dictionary of Physics* immediately upon publication.

8000 pages,
Complete set of nine volumes, $298.00

A Short Course in Organic Chemistry, 2nd Edition

HAROLD HART and ROBERT D. SCHUETZ

Michigan State University

- an integrated presentation of aliphatic and aromatic chemistry.
- emphasis on commercial and biochemical applications of organic chemistry.
- illustrated with outstanding drawings and photographs.

346 pages *1959* *$6.50*

A Laboratory Manual for

A Short Course in Organic Chemistry, 2nd Edition

NOW IN A NEW EDITION . . .

EXPERIMENTAL PHYSICAL CHEMISTRY

Second Edition

By W. G. Palmer

This text is tailored to the needs of beginning students at the college level—teaching basic principles through laboratory demonstration, presenting experiments designed for the typical three-hour lab period, reasonable in its prescriptions for equipment.

Reviewers called the first edition as good as any comparable text and praised the clarity of its presentation, which renders demonstrators almost superfluous. Its successor, revised to encompass recent discoveries, is its equal in every way. $5.50

CAMBRIDGE UNIVERSITY PRESS
32 East 57th Street,
New York 22, New York

NEW · 1963 · MODERN

COLLEGE CHEMISTRY, FOURTH EDITION

Laboratory Experiments in General Chemistry, Second Edition

G. Brooks King, *Washington State University*
William E. Caldwell, *Oregon State University*

The Text (637 pages):
- Carbon-12 basis for all atomic weights.
- Electron orbitals and energy levels in discussion of atomic structure.
- Complete treatment of chemical bonds, stoichiometry, and transition elements.

The Lab Manual (368 pages):
All experiments revised in accordance with latest theoretical developments. Macro and semimicro qualitative analysis.

A BRIEF COURSE IN SEMIMICRO QUALITATIVE ANALYSIS

Second Edition · 1961

For laboratory instruction on the semimicro scale

SEMIMICRO EXPERIMENTS IN GENERAL CHEMISTRY AND QUALITATIVE ANALYSIS

by **Nicholas D. Cheronis,** Formerly of Brooklyn College and **Herman Stein,** Bronx Community College, both of The City University of New York.

An established laboratory manual which is suited for use with most textbooks. Numerous exercises allow the instructor a range of selection from quantitative experiments to Qualitative Analysis sufficient for a quarter or semester.

310 pages 85 illustrations $4.00

SEMIMICRO EXPERIMENTAL ORGANIC CHEMISTRY

by **Nicholas D. Cheronis,** Formerly of Brooklyn College

A modern laboratory text, considered a classic in its field. The stress is on organic techniques as well as on the chemistry of the preparations and reactions.

410 pages 89 illustrations $5.50

Write for examination copies to

THE HADRIAN PRESS

667 MADISON AVE. NEW YORK 21, N. Y.

CHEM SOURCES

5th Edition now available with 4,000 new chemical listings

Chem Sources is the most complete chemical source guide ever compiled. Over 28,000 listings of chemicals and allied products.

Regardless of your field of research, you will find the organic or inorganic that is wanted listed in **Chem Sources.**

Price: $25.00 per copy

Chem Sources is available for 14 days free examination from

Advances in Chemistry Series 34 through 41

Buy these books for a multi-phased treatment of important developments in chemistry and for invaluable reference data. None of the papers presented here is published anywhere else.

34. POLYMERIZATION AND POLYCONDENSATION PROCESSES 1962
260 pages. Paper bound. $8.00

35. AZEOTROPIC DATA—II 1962
by Lee H. Horsley and William S. Tamplin
100 pages. Paper bound. $4.50

36. FREE RADICALS IN INORGANIC CHEMISTRY 1962
175 pages. Paper bound. $7.00

37. REACTIONS OF COORDINATED LIGANDS AND HOMOGENEOUS CATALYSIS 1963
255 pages. Paper bound. $7.00

38. SALINE WATER CONVERSION—II 1963
199 pages. Paper bound. $6.00

39. NONSTOICHIOMETRIC COMPOUNDS 1963
253 pages. Paper bound. $7.00

40. MASS SPECTRAL CORRELATIONS 1963
by Fred W. McLafferty
117 pages. Paper bound. $4.75

41. NEW APPROACHES TO PEST CONTROL AND ERADICATION 1963
73 pages. Paper bound. $3.75

FAMOUS CHEMICAL REFERENCE

Greatly Expanded in Size and Scope

One of the most complete listings of chemicals and drugs in the English language. Contains approximately 10,000 monographs, providing concise information on organic and inorganic compounds. Gives structural formulas, empirical formulas, molecular weights and percentage composition. Encyclopedic in scope. New cross-indexing system makes it easy to locate a given substance, regardless of synonym with which user is familiar.

Luxuriously bound
Contains 1600 pages • $12.00

AVI Books On FOODS AND FOOD PROCESSING

Fundamentals of Food Engineering
By Stanley C. Charm, *Massachusetts Institute of Technology.* An exposition of the principles governing the design, operation and control of food processes.
650 pp. $24.50 domestic; $25.50 foreign

Microwave Heating — In Freeze Drying, Electronic Ovens and Other Applications
By David A. Copson, *University of Puerto Rico.* The principles of microwave heating and the use of electronic ovens for food cooking and processing are presented.
432 pp. $11.00 domestic; $12.00 foreign

Technology of Food Preservation
By Norman W. Desrosier, Director of Research, *Beechnut-Life Savers, Inc.* A simple consideration of the fundamental principles and methods of preserving foods. 2nd Edition.
418 pp. $9.50 domestic; $10.50 foreign

Radiation Technology in Food, Agriculture and Biology
By Norman W. Desrosier, Director of Research, *Beechnut-Life Savers, Inc.,* and Henry M. Rosenstock. An exposition of the practical uses of radiations produced by linear accelerators and radioactive isotopes.
401 pp. $12.50 domestic; $13.50 foreign

Fundamentals of Quality Control for the Food Industry
By Amihud Kramer and Bernard Twigg, *both of University of Maryland.* The principles and technics of quality control in food processing are outlined.
512 pp. $14.75 domestic; $15.75 foreign

The Chemistry and Technology of Cereals as Food and Feed
By Samuel A. Matz, *Borden Company.* A consideration of the composition and utilization of cereals.
732 pp. $15.00 domestic; $16.00 foreign

Food Texture
By Samuel A. Matz, *Borden Company.* An exposition of factors controlling texture of all kinds of foods.
350 pp. $11.50 domestic; $12.50 foreign

Food Flavorings—Composition, Manufacture and Use
By Joseph Merory, President, *Merory Flavors.* Complete information about all flavorings, both natural and artificial, is presented.
370 pp. $12.50 domestic; $13.50 foreign

Food Enzymes
By Harold W. Schultz, *Head of Food Technology Dept., Oregon State University.* Proceedings of a Food Symposium held at Oregon State University.
158 pp. $6.75 domestic; $7.50 foreign

Symposium on Foods—Lipids and Their Oxidation
By H. W. Schultz, E. A. Day, and R. O. Sinnhuber, *all of Oregon State University.* Proceedings of the 1961 Food Symposium held at Oregon State University.
420 pp. $3.00 domestic; $3.50 foreign

Fruit and Vegetable Juice Processing Technology
By Donald K. Tressler, *President, Donald K. Tressler and Associates,* and Maynard A. Joselyn, *University of California.* Complete information on the composition and technology of all fruit and vegetable juices is presented. 2nd Edition.
1040 pp. $19.75 domestic; $20.75 foreign

Practical Food Microbiology and Technology
By Harry B. Weiser, *Ohio State University.* A practical book concerned with the microbiological aspects of food processing.
305 pp. $11.00 domestic; $12.00 foreign

10-day Free Examination of All Books

"I am impressed with your

COLLECTED READINGS in INORGANIC CHEMISTRY

and intend to use it as an auxiliary reference in two inorganic courses which I am teaching"

Inorganic chemical research is moving so rapidly that keeping abreast of developments is increasingly difficult for student and teacher. During the past five years many review articles written specifically to serve this purpose have appeared in the pages of the *Journal of Chemical Education.*

Twenty of the country's most prominent professors of inorganic chemistry indicated the articles they have found most useful; 41 of their most frequent choices have been collected in this volume. Various aspects of Coordination Chemistry are treated by 14 articles. Five deal with Inorganic Polymers, six with Non-Aqueous Systems, and five with topics in Solid State Chemistry. The remainder discuss miscellaneous topics from nucleogenesis to chromatographic behavior of metallic ions.

The popularity of these papers has been demonstrated by the demand for reprints, often far beyond the authors' supplies. The convenience and low multiple-copy price of this volume of collected papers makes it a most valuable supplement to existing textbooks. Every student can now have on his bookshelf the authors he recognizes to be authoritative specialists: Nyholm, Sutton, Bailar, Pearson, Eyring, Audrieth, Burg, Sisler, Honig, Coryell, and many others.

$3.50 EACH

Special quantity prices for students use:

10–19 copies . . . . . **$3.25 each**

20 or more copies . . . . . **$3.00 each**

The BIG

6th EDITION

DISCOVERY of the ELEMENTS

by Mary Elvira Weeks

COMPLETELY REVISED and RE-WRITTEN!
Brought up-to-date to include all the exciting new discoveries of the past decade . . . the author has re-written every chapter, stressing the significance of early discoveries in terms of what we know today and incorporating all the new factual and anecdotal material that has come to light.

SPECIAL CHAPTER ON ELEMENTS DISCOVERED BY ATOMIC BOMBARDMENT By Henry M. Leicester, Ph.D.

328 PAGES LONGER THAN FIFTH EDITION! Packed to the covers with fascinating and entertaining new material.

GREATER READABILITY! Completely new format and type style have been employed to assure easy-to-read ligibility throughout.

TEACHER, STUDENT OR SEASONED CHEMIST, reading for enjoyment only, will find Discovery of the Elements an unusual treat. Rarely has so much instructive information been presented in such delightfully entertaining fashion!

920 pages **$10.00 postpaid**

The National Catalog of Patents

THE detailed accomplishments of international science and technology are nowhere so completely described as in the patent literature of this country. To make this complete wealth of information conveniently and economically available to the engineering, industrial, and scientific community, Rowman and Littlefield, in cooperation with the United States Patent Office, has embarked on the publication of *The National Catalog of Patents.*

Rowman and Littlefield, Inc., with its unique experience in preparing massive compilations, is especially geared to undertake a project of this nature and scope. We have for years been the publisher of the *Library of Congress Catalogs,* of which we now have 283 volumes in print, with an additional 54 volumes in preparation. This is a monumental work listing and describing all printed books deposited in the Library of Congress from 1898 to date.

The National Catalog of Patents draws together in orderly classification, and highly workable form, the massive body of patent information diffused throughout the more than five thousand issues of the *Official Gazette* of the United States Patent Office.

In it you will find all the patents in a given area of interest grouped together by Classes and Subclasses as defined by the Patent Office. Patents granted in their respective fields (as well as allied patents which have primary listing in other fields) are shown in the form of one major claim and one drawing as exemplified in the *Official Gazette.* This inevitably results in an expansion of search horizons. Each unit of the *Catalog* contains its own *Manual of Classification,* Subject Index, Index of Cross References, and Numerical Index. In every step of its preparation the *Catalog* has benefited immeasurably from consultation with the Patent Office.

Plan of Publication

The National Catalog of Patents is being published in accordance with the grouping system followed by the Patent Office. Our schedule calls for first publishing the following groups: **I. Chemical** and Related Arts; **II. Electrical,** including Communications and Radiant Energy; **III. Mechanical** Manufacturing and Machine Element Arts. Volumes covering **Chemical 1961** and **Electrical 1961** are now ready.

The publication of the complete *Catalog* will require many months of arduous preparation, but as an interim solution to the information retrieval problem we offer:

The Index of Patents

1790-1960

Including Cross References and Allied Patents

This compilation of patents by number is intended to serve as a complete guide to the vast body of patent information. It is not meant to be a replacement for our *National Catalog of Patents* but rather a precursor that can, by itself, be profitably used until the *Catalog* itself is ready. It should then serve as a valuable adjunct to the main works.

In the *Index,* each patent number is listed under the class and subclass number and descriptive heading under which it is *now* classified by the Patent Office. Its scope, in each field of interest, will cover the period from the granting of the first patent in that field (in CHEMICAL this dates back to the first patent issued—in 1790) up to the end of 1960. From 1961 on our yearly *Catalog* units take over the job.

It will be issued in the same sequence as outlined above for *The National Catalog of Patents* with the first three units to be as follows: CHEMICAL (six volumes); ELECTRICAL (five volumes); MECHANICAL (five volumes).

Board of Editors

KALMAN M. HELD, PH.D., *Chairman*
LEONARD R. SOLON, PH.D.
JAMES G. BECKERLEY, PH.D.
GEORGE HORNBY, *Editorial Director*
KARL L. BROOKS, M.A., *Managing Editor*

A descriptive brochure will be sent on request.

STOP! INJURIES and WORK INTERRUPTIONS

from falling fluorescent tubes with DEN-EL *Safety Guards*

Fluorescent tubes sometimes shatter . . . or vibration and shock can release them from fixtures. The risk of physical injury, poisoning, contamination, spoilage and loss of time is ELIMINATED FOREVER, for just a few pennies for each tube, when DEN-EL SAFETY GUARDS are used.

They install easily, quickly, with just a screw driver. Permanent, positive protection. Made of Rustproof Stainless Steel, Non-Magnetic. Just two guards for each lamp.

Types for all tubes and fixtures — order direct by Style No.

	Per 100	Per 1000
EST-12 — Fits all T-12 lamps for strip lighting and commercial units.	$12.50	$105.00
EST-12A—Fits all 40 watt T-12 Bi-pin lamps with open end units	$12.50	$105.00
HST-12 — Fits all T-12 lamps for units with narrow channel	$12.50	$105.00
AST-17—Fits all T-17 800 and 1500 MA Power Groove tubes, for strip lighting and industrial units	$14.00	$120.00

MEL-TEMP® MEASURES CAPILLARY MELTING POINTS

- room temperature to 400°C
- 500°C with special thermometer
- rapid heating and cooling
- one to three samples

MEL-TEMP is an integrated capillary melting point apparatus whose heater is controlled by a variable transformer. Excellent viewing is provided by a built in light and a 6-power lens. The attractive gray hammertone base occupies 4" x 5".

only $97.50 Includes vial m.p. capillaries and 0-400°C thermometer.

HITACHI PERKIN-ELMER ULTRAVIOLET VISIBLE GRATING SPECTRO-PHOTOMETER

The Model 139 Grating Spectrophotometer, a compact, precise modern instrument, out performs similar spectrophotometers costing significantly more.

Check these features: High resolution grating Monochromator — gives exceptional radiation purity in transmittance / absorbance measurement from 205 to 800 millimicrons; Direct reading meter — presents measurements in both transmittance and absorbance quickly and accurately; Single wide-range phototube — covers the entire range from 205 to 800 millimicrons, eliminates need to change even at wavelength extremes; Dual Hydrogen/Tungsten lamp source assembly — has high energy output, gives instant switching from one source to the other; Direct line-operated power supply — is stable, fully transistorized, eliminating batteries and drift problems; Low cost — brings the advantages of modern instrumentation to any laboratory with unmatched economy and superior performance.

The five basic functional units, in combination, provide the analyst with a fully integrated instrument for the rapid and precise analysis of any sample by absorption measurement.

Thomas *announces the outstanding new . . .*

Hitachi Perkin-Elmer MODEL 139 SPECTROPHOTOMETER

- ▶ *Monochromator resolution 0.2 millimicrons*
- ▶ *Range 195 to 800 millimicrons*
- ▶ *Line operated*
- ▶ *Excellent stability*

for immediate shipment from our stock

SPECTROPHOTOMETER, Hitachi Perkin-Elmer Model 139 UV-VIS (Ultraviolet-Visible Range). Diffraction grating type, compact modular construction, completely a.c. line operated, range 195 to 800 mμ, meter indicating directly in transmittance and absorbance, for precise research or control use. Excellent design and workmanship provide an instrument of outstanding accuracy, stability, and versatility.

Wide Range Phototube. A single tube, with detectors of antimony-cesium and silver-cesium, covers entire range from 195 to 800 mμ.

Energy Recording and Kinetic Studies. The exceptional stability of this instrument makes it especially suitable for these techniques.

Linear Wavelength Control. Easily read dial has uniformly spaced divisions over 1 mm wide, corresponding to 0.5 mμ.

Meter Scale Expansion—Absorbance-transmittance meter scale has 10× expansion switch.

Mirrored Meter Scale, 5½ inches long

Performance Specifications

Wavelength range—195 to 800 mμ.

Resolution (monochromator)—0.2 mμ (2Å) throughout range.

Photometric accuracy—better than ±0.5% transmittance; better than ±0.006 absorbance at 0.4 absorbance.

Slits—continuously adjustable from 0.005 to 3.0 mm. Height 20 mm.

Wavelength accuracy—better than ±0.5 mμ throughout range.

Wavelength reproducibility—better than 0.1 mμ.

Photometric reproducibility—better than 0.002 absorbance between 0 and 0.5.

Cell path—5 mm, 10 mm, or 20 mm, in standard, 4-place holder.

9096-E. MODEL 139 SPECTROPHOTOMETER, as described. Complete with a.c. power supply, installed hydrogen and tungsten lamps, 4-place cell holder, matched set of 4 fused silica 10 mm absorption cells, etc. For 115 volts, 50 or 60 cycles, a.c. 2,300.00

THOMAS DIGITAL READOUT, with numerals approx. ½-inch high, available for use with above. Details on request.

REINHOLD books

Bobbitt:
THIN LAYER CHROMATOGRAPHY

by JAMES M. BOBBITT, Assistant Professor of Chemistry, University of Connecticut. 6 × 9. 1963. 250 pp., $8.50

-No aspect of analytical chemistry has made more dramatic strides in recent years than chromatographic techniques. This new book on thin layer chromatography is compiled and organized in such a way as to keep pace with increasing interest and widening usage. It has been designed to serve those just beginning to apply TLC to their problems, as well as to provide a complete reference encompassing current data and basic material. Because of the rapidly attained popularity of TLC in Europe, standardized adsorbent and equipment have become available commercially. It has become important to have a knowledge of appropriate "sets"—as well as their sources. To provide the knowledge, and to further the application of theory, the author discusses each experimental technique in detail—covering procedures, types, various binders—listing numerous reagents with specific directions for preparation.

Now it is possible to find previously unattainable material on: preparing the layers; such parameters as thickness and moisture contrast; various glass plates used; a comparative analysis of various commercially available apparatus given (with sources)—accompanied by detailed drawings; descriptions of layer preparation, with directions. The contents also include making the separations: general requirements for separation vessels and sources; application of the mixtures to be separated; development of the chromatograms, reliability of Rf values in various systems. The section on analysis of the results covers spray reagents, other methods for making the compounds visible, and component isolation. Applications include types of problems which can be solved: specific applications, organic, biochemical, and inorganic.

-In addition to theoretical considerations, the history of the development of the method of thin layer chromatography is outlined with the persons involved cited. There is full consideration of the new application of chromatographic analysis. Not only are the advantages and disadvantages of this recently discovered technique carefully weighed, but its relation to other forms of chromatography are projected within the framework of the entire subject as a whole.

Heftmann:
CHROMATOGRAPHY

edited by ERICH HEFTMANN, National Institutes of Health, Bethesda, Maryland. 1961. 780 pages. $17.50

"Dr. Heftmann together with 33 outstanding research workers in the field of chromatography has compiled a book which deals equally with adsorption, ion exchange and partition chromatography, gas chromatography and zone electrophotesis. Each chapter is written by a different author, some chapters having been translated by Dr. Heftmann. The book will be invaluable for anyone teaching or learning chromatographic methods, as it presents a survey of most of the possibilities of this technique. It can also be recommended as a handbook in certain fields. The text is richly illustrated, well printed and some chapters list good selections of Rf values and Electrophoretic mobilities."—Journal of Chromatography

The first half of the book contains an authoritative development of the theories and techniques of chromatographic methods; the second half deals with the applications to important classes of compounds. A wealth of references to current papers, books and review articles is included.

Stock and Rice:
CHROMATOGRAPHIC METHODS

by R. STOCK and C. B. F. RICE. 1963. Approx. 250 pp., $10.00

With emphasis on paper and gas chromatography, because these methods are now the most important, this well-organized book serves as an introduction and accounting of techniques currently in use. The treatment is primarily dictated by practical considerations, and is designed to show how the various methods complement each other. In addition to this wealth of practical detail is the extensive knowledge which reflects the authors' personal experience over a long period of time. One important and invaluable feature is the inclusion of a group of single experiments covering the whole range of methods described, especially students' experiments in gas chromatography which is regarded as an important development. Zone electrophoresis, while not strictly speaking a chromatographic technique, is nearly enough related to be included. The reader can find guidance as to the choice of method for a particular purpose, and to assess the relative value of the different procedures.

A book valuable to teachers in schools, technical colleges and universities, to final year undergraduates, and to analytical and industrial chemists and biochemists who want an introduction to chromatography.

Topics in . . .

Chemical Instrumentation

. . . a Chem Ed feature

Edited by **S. Z. LEWIN,** New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

XII. Pressure Measurement. Part Two

Seymour T. Zenchelsky, *School of Chemistry, Rutgers University New Brunswick, N. J.*

The preceding installment dealt with liquid-column gages; this one treats mechanical and thermal gages.

Mechanical Gages

One great disadvantage of liquid-column gages is the fact that chemical reactions may occur between the manometric liquid and the gas whose pressure is being measured. In the case of mercury, the solid products of such reactions frequently deposit on the inner walls of the tubes and reduce the accuracy of measurement. This is the reason for the great concern with ease-of-cleaning as a feature in the design of such devices. Mechanical gages, on the other hand, eliminate the manometric liquid, exposing to the gas a solid surface which can be metal, glass, or quartz.

Such gages depend upon the distortion of the solid surface when unequal pressures are exerted on its two sides, thus these gages may be used as either absolute or differential manometers. Since at equilibrium the forces acting on both sides of the surface must be equal, it follows that the sensitivity of the gage will increase with increased surface area. Four types have been used: (1) the Bourdon tube, (2) the bellows, (3) the capsule, and (4) the diaphragm. These are illustrated in Figures 15, 16, 17, 18, and 19. For sufficiently large pressure-differentials, the distortion may be measured by means of the displacement of a pointer which is linked mechanically to the surface, otherwise displacement transducers are needed.

Bourdon Tube. The basic Bourdon tube consists of a length of tubing, elliptical in cross-section, which is bent into an arc and sealed at one end. If the open end is connected to a source of high pressure, the cross-section of the tube will tend to become more nearly circular, resulting in an increase of the radius-of-curvature of the arc. Thus, if the open end of the tube is constrained, the closed end will be displaced. Greater sensitivity is obtained by increasing the length of the Bourdon tube in order to increase its area, but space is conserved by winding the tube into a spiral or helix (Fig. 20 and 21). The effect of barometric pressure (on the outside of the Bourdon tube) is either compensated by the use of a second Bourdon tube, which is open to the atmosphere, or eliminated by sealing the instrument case at fixed pressure.

Figure 15. Wallace and Tiernan Bourdon-tube gage mechanism.

Bourdon tubes are less sensitive than the other mechanical pressure-sensing devices, and are normally used for measurements above one-atmosphere (approximately 760 mm Hg). Direct-reading gages are available from many laboratory-supply companies, with Bourdon tubes made of various metals and alloys (Fig. 22). More sensitive Bourdon-gages, made of glass or quartz, are available from fabricators of custom laboratory-glassware. The Worden gage (Worden Laboratories, Houston 27, Texas) consists of a quartz helix which possesses a sensitivity of 360-degrees of rotation per atmosphere (Fig. 23). This motion may be followed either by observing an attached pointer through a microscope or by observing the displacement of a light-beam which is reflected from an attached mirror. The latter method provides greater sensitivity through the available optical leverage.

Figure 16. Taylor Instrument absolute-pressure bellows element.

Figure 17. Bristol capsular measuring element.

HIGH RESOLVING POWER APPARATUS

HILGER & WATTS

The development of the maser and laser has substantially broadened the use of high resolving power apparatus. Hilger & Watts now provide a comprehensive selection of equipment to meet the increased requirements.

Among the more important are etalon and interferometer plates — ranging from 20 mm. aperture to 100 mm. aperture; with flatnesses to 1/200 of a wavelength. Mounts for these plates, as well as wave length spectrometers designed to accommodate etalons within the instrument, are standard stock items.

Other new developments include: motor driven Fabry-Perot and Michelson interferometers with fringe counting and amplitude measuring equipment; dielectric coatings for all plates. Lummer-Gehrcke plates and transmission echelon gratings are also available.

Illustrated Top Right—
B345 100 mm. Aperture Etalon

Illustrated Center Right—
D186 Spectrometer with Etalon mounted

Illustrated Center Left—
D260 Large Aperture Spectrometer with Etalon

no vapor condensation in these new LaPine VACUUM MASTER (TM) high vacuum pumps . . . made by Leybold!

Prolonged pumping time, limited ultimate vacuum obtainable and annoying oil contamination are but a few of the frustrations one is apt to meet when using ordinary high vacuum pumps. The villain committing these dastardly deeds is Vapor Condensation! The excessively high compression ratios high vacuum pumps must achieve in order to discharge gases from the vacuum system—often as high as 760:1—compress vapor particles so greatly that they condense to form droplets. As a result, the exhaust valve is not forced open by pump pressure and exhausting does not take place.

In LaPINE Vacuum Master High Vacuum Pumps, fresh air—gas ballast—drawn from the outside, solves the problem. Excess pressure in the pump required to open the exhaust valve is produced before water particles can condense. Vacuum Master pumps may be operated first with the gas ballast valve open to remove vapor—then run with the valve closed to obtain desired higher vacuum.

CHOOSE THE LaPINE Vacuum Master PUMP TO MEET YOUR EXACT REQUIREMENTS . . . Four are available: Single-Stage, models 2S and 6S; Two-Stage, models 2D and 6D. All are manufactured by E. LEYBOLD's Nachfolger of West Germany, incorporate the most recent developments in pump design, and carry forward the 100-year-old LEYBOLD TRADITION of precision-manufacture, fine performance and absolute reliability.

Some of their superior features: Low ultimate pressure . . . Low noise level . . . High water vapor tolerance . . . Gas ballast operation at the twist of a knob . . . Visible oil level . . . No oil foaming . . . and Connections in seconds with small-flange fittings. Write today for your copy of the complete "LaPINE Vacuum Master High Vacuum Pumps" bulletin.

Absolute or ultra-sensitive differential readings

A simple, compact Micrometric Manometer* at low cost.

This instrument combines the best features of an RGI high-precision micrometer assembly and a positive closed end manometer to produce a range of 0-2" in .002" divisions, sensitivity of .0005", and excellent visibility. Precision-bore glass fabrication throughout.

Use mercury for direct absolute or differential readings, or low-density manometric liquid for ultra-sensitive differential readings.

Model G-1500 (without mercury) priced right where you want it at $49.50.

Write today for our new catalog.

Four reasons why the new H6 saves time and money

- A new 100 scale division micrometer permits direct reading to .1 mg without estimation.
- The 1200 mg optical range is the largest available in any analytical balance.
- Only 2 knobs control all weight combinations up to the full 160 g capacity.
- A patented damping system rapidly brings the balance into equilibrium.

This new Macro-Analytical Balance features a 1200 mg optical range, ± 0.05 mg precision and direct reading to .1 mg. It can be operated by unskilled laboratory personnel, liberating skilled specialists for other work; it reduces the sources of error in analytical work; and it makes weighings fast!
If you would like to try this new balance, or want more detailed information, contact your Mettler dealer now, he will be glad to arrange a demonstration or trial.

Figure 21. Taylor instrument helical Bourdon-tube element.

Figure 22. Wallace and Tiernan Bourdon-tube gage.

tivity, are available from Wallace and Tiernan, Consolidated Vacuum Corp. (Rochester 3, New York), and Arthur F. Smith, Inc. (Rochester 4, New York). Two of these are shown in Figures 24 and 25. The Wallace and Tiernan Absolute Pressure Indicator is available with a range of 0.1–2 mm Hg and with graduations of 0.1 mm Hg. It has an accuracy of 0.33% of full-scale range.

Recording and Control. Mechanical gages possess a second advantage over liquid column gages: they lend themselves more readily to continuous indication, recording, and control. For these purposes a variety of displacement transducers is used; some of them are described below.

The Texas Instruments Precision Pressure Gage (Texas Instruments, Inc., Houston 6, Texas) uses a fused-quartz Bourdon-helix with attached mirror (Fig. 26). Displacements are detected photoelectrically, resulting in the unbalance of a bridge circuit. By manually balancing the bridge, a sensitivity of 1×10^{-4} atmosphere can be achieved over the range 0–1 atmosphere. A digital readout minimizes reading errors (Fig. 27). The instrument has recorder terminals for continuous monitoring of the bridge unbalance.

In the Fischer and Porter Press-I-Cell Indicator (Fig. 28), the Bourdon-spiral (or capsule) is attached to an iron rod which forms the core of an inductance coil. Motion of the rod results in the unbalance of an a.c.-bridge, with the consequent restoration of balance by means of a servo system. This instrument is available in the ranges, 0–800 mm Hg (absolute)

GRADE #M18 PURE GUM

GRADE #M35 GREEN NEOPRENE

GRADE #M29 BLACK RUBBER

Who says stoppers can't be improved! Now the new Molded Products Division, supported by the research facilities of America's leading elastic thread manufacturer, presents an imaginative new line of stoppers for your laboratory . . . softer, more resilient BLACK RUBBER that seals better, prevents breakage and freezing; isoprene PURE GUM that floats and keeps its shape for long life; new GREEN NEOPRENE, a sulphur-free stopper that withstands 150°C temperatures! All come in five-pound packages and are available in convenient one-pound packs, if you prefer. This full line includes equally outstanding supplementary rubber supply items. All are made by new equipment from brand-new molds. All are backed by the century-old reputation of Easthampton Rubber Thread Company for constant quality and service.

Molded Products stoppers are available now at your laboratory supply house. For free samples and full information, write Department RLS.

Figure 24. Consolidated Vacuum diaphragm gage.

Absolute Pressure Potentiometers (Bourns Laboratories, Riverside, California) consist of evacuated capsules which are mechanically linked to a slidewire potentiometer (Fig. 29). They are available in the range, 0–2 lb/in.^{2} (approximately 0–100 mm Hg), with a resolution of 0.25% of full-scale range and an accuracy of 0.5% of full-scale range. A differential pressure-potentiometer covering the range, 0–1 lb/in.^{2}, with similar accuracy, is also available. These devices can be obtained in several resistance ranges, and their outputs vary linearly with pressure to within 1% of full-scale range. For higher pressures, a Bourdon-tube potentiometer is also available.

Pressure-transducers, consisting of

BEST BUY: MODEL 139

NEW MODEL 139 ULTRAVIOLET-VISIBLE SPECTROPHOTOMETER —BY ANY STANDARD GIVES MORE PERFORMANCE AT LESS COST

At no extra cost 1 Full coverage of ultraviolet and visible ranges. 2 Transistorized line-operated power supply. 3 High dispersion difraction grating optics. 4 Direct reading in transmittance and absorbance. 5 Precision scale expansion. 6 Linear wavelength output. Normal operating range is 205 to 800 millimicrons for transmittance measurement.

Optional All attachments for ultraviolet and visible spectral analysis, plus such *exclusive* attachments as atomic absorption and emission photometry.

Pooling two decades of experience in spectroscopic equipment, Perkin-Elmer and Hitachi Limited have joined to create this modern spectrophotometer.

We believe that the result of this joint effort is the finest instrument of its type available anywhere in the world. Price: $2300 delivered to your laboratory anywhere in the United States.

Please write for a complete brochure and price list on this new instrument to Instrument Division, Perkin-Elmer Corporation, 870 Main Avenue, Norwalk, Conn.

New Torsion 1,000 gram balance speeds laboratory work

Only Torbal 1/10 gram PL-1 offers all these features

- *Fast, accurate readings optically projected to 1/10 gram*
- *No-knife edge construction eliminates friction and wear*
- *Greater taring range*
- *Remains unaffected by out-of-level conditions*
- *Oil dampened to speed weighings*

Price only $525.

To give you more convenient, accurate readings, Torsion has designed the PL-1 with a fine-reading vernier to 1/10 gram and a capacity of 1 kilogram. The balance has an optical range of −10 grams to +110 grams.

The heart of the mechanism in the new PL-1 is the Torsion no-knife edge construction. This eliminates friction and wear, insures lifetime accuracy and speeds weighing. The balance will operate accurately even in severely corrosive or dust-laden atmospheres.

Taring through a 125 gram range is accomplished with a built-in knob on the side of the balance. By using the second pan the balance can be made to tare up to 325 grams. Torsion's optical projection Model PL-1 offers a sharp image with a high degree of illumination for easy reading and an oil damper to speed up weighing.

Figure 29. Bourns Laboratroies pressure potentiometer.

California) and forms the basis for its Absolute Pressure Transducer. This instrument consists of a sandwich of the paint (between a pair of metal discs). Since the resistance of the paint changes with pressure, the device acts as a differential manometer (or as an absolute manometer when the reference pressure is zero). Although this transducer defies classification according to the scheme given in Part I, its listing among mechanical gages appears reasonable.

Figure 30. Consolidated Electrodynamics strain-gage pressure transducer

The Clark Absolute Pressure Transducer is sensitive from approximately 800 mm Hg down to 15 mm Hg, exhibiting a resistance variation of 4×10^5 ohms over this range.

Thermal Gages

Thermal gages depend upon the fact that the heat conductance of a gas varies with its pressure. Thus the temperature of a heated surface, which is surrounded by gas, will decrease with increased gas pressure. These are, therefore, gages of the third kind: they depend upon the kinetic-molecular behavior of gases. Their

moduline

a new Aerograph series

Hy-Fl2 • 202 • 1520

How can you design a gas chromatograph and protect heat-sensitive electronic components from the oven heat? One cumbersome method is to build two separate units.

A separate cabinet fan in a single, compact unit is the approach used in the new Aerograph Moduline Series.

Three sparkling models were developed.

THE "Hy-Fl2" is a single-column instrument which adapts perfectly to: Flame, Electron Capture, Cross Section and Thermal Conductivity detectors. Manual or linear temperature programming modules are optional.

THE "202" is a two-column instrument adaptable to both Dual Flame and Thermal Conductivity detectors. Manual or linear temperature programming modules are optional.

THE "1520" is a deluxe version of the 202 equipped with both Dual Flame and T.C. detectors. It features matrix board temperature programming, automatic cooldown, and automatic reset-to-start temperature.

The 1520

The 202

The Hy-Fl2

CC-0. In Public Domain. Guru

Digitized by Arya Samaj Foundation Chennai and eGangotri

The 202

FEATURES

- Dual-column with either flame or T.C. detectors
- Linear or manual programmer modules
- Automatic oven cool-down (with LP)
- Dual input electrometer or bridge modules
- On-column or flash vaporized injection
- Separately heated detector oven

ORDER:

1. 202—FL/MP—dual flame—manual programmer
2. 202—TC/MP—thermal conductivity—manual programmer
3. 202—FL/LP—dual flame—linear programmer
4. 202—TC/LP—thermal conductivity—linear programmer

THEORY

The concept of two-column gas chromatography was first introduced by Drs. Edward M. Emery and W. E. Koerner, Monsanto Chemical Co., at the 1961 Spring ACS Meeting.

At about this same time we introduced the Aerograph A-350 featuring dual-columns connected to a four-filament T.C. cell and having separate injectors for each column. The basic advantages of the two-column system are:

1. Column bleed compensation is provided by using one column as a blank.
2. Different column packings give the chemist immediate use of two-type columns such as polar and non-polar.

Two new basic dual-column gas chromatographs, 202 and 1520, have been developed. Both instruments have flow controllers, flow meters, and long tapered metering valves for controlling gas flow to each column.

The separate detector oven is carefully regulated at four set temperatures. The all stainless steel column oven, heated by a 800 watt coil, will program at 35°C/min to 400°C and will cool from 400 to 100°C in four minutes.

The Aerograph 202 incorporates either dual flame or dual input detectors. It may be used with the manual temperature programmer or the simple linear tempera-

MODULINE COMPONENTS

1	Fan for cabinet cooling
2	Synchronous motor, rubber-mounted
3	Fan for oven air circulation
4	Dual-column position
MLTP	Matrix linear temperature programmer

The 1520

PRACTICE

ture programmer (LP) modules. With the LP, oven cool-down is automatic but door-close is not. A manual switch operates the door at any time.

The 1520 is a more deluxe version of the 202. It contains both the dual flame and thermal conductivity detectors. The detector choice is made by re-connecting the downstream ends of the column. The exclusive Aerograph matrix temperature programmer is standard. This deluxe programmer not only gives complete flexibility in pre-setting temperature programming rates but automatically closes the oven door after cool-down and re-establishes the start temperature.

The injectors are independently heated. Temperature readout on an accurate, compensated pyrometer reads column oven, detector oven, injector, collector and auxiliary equipment plug. An automatic upper oven temperature limit control on all Moduline instruments protects columns and equipment from accidental overheating.

At lower right is shown a typical temperature program profile. The program rate may be caused to increase at any time during analysis or may be pre-set before the analysis. The programming rate is established by the resistance value of the matrix plugs . . . the time of change by their position on the matrix board.

At lower left is an interior view of the 1520 showing cabinet air cooling and modules. The 202 is identical to the "A" portion. Modules in this case would be either electrometer or bridge • manual programmer or linear programmer.

FEATURES

- Dual-column with both flame and T.C. detectors
- Matrix board temperature programmer
- Automatic oven cool-down and re-set to start temperature.
- Both dual input electrometer and bridge modules
- On-column or flash vaporized injection
- Separately heated detector oven

ORDER:

Aerograph 1520—dual column gas chromatograph with both dual flame and T.C. detectors. Flow controllers, electrometer, bridge/power supply and matrix temperature programming modules are standard.

MATRIX TEMPERATURE PROGRAMMER

A	Pre-set temperature—70°C.
A-B	Isothermal operation—@ 70°C for 3 min.
B-C	Linear programming—@ 5°C/min for 5 min.
C-D	Isothermal operation—@ 95°C for 4 min.
D-E	Linear programming—@ 20°C/min for 5 min.
E-F	Isothermal operation—@ 195°C for 10 min.
F-G	Door opens and oven cools down to 60°C in 7 minutes pre-set by timer.
G-H	Door closes and oven heats to pre-set temperature—70°C.

Digitized by Arya Samaj Foundation Chennai and eGangotri

The Hy-Fl$_2$

The Hy-Fl$_2$, a big brother to the popular Hy-Fl 600-C, is a single column instrument which adapts perfectly to the three common ionization detectors and to the four-filament Thermal Conductivity detector.

Hy-Fl$_2$ Dual Channel

A further interesting option incorporates both flame and electron capture detectors. With this combination the column effluent is divided by a stream splitter to feed both detectors. The signals from both detectors are amplified by a two-channel electrometer which in turn operates a two-pen recorder. A striking trace of peppermint oil was made with this equipment. Many peaks were exhibited by electron capture which were not detected by the flame because of their low concentration. Please write for details.

BONUS FEATURES

- Separate detector oven, heats to 400°C.
- 2" injector, stainless, separately heated.
- Variable power and thermocouple plug for auxiliary injection equipment.
- Stainless column oven, heats 40°C/min.
- Sample collection—capillary, with Flame Det.
- Carrier gas flow controller with long, tapered needle valve.

Manual Temperature Programmer—This unique controller supplies constant power to the column oven, by a solid-state electronic, adjustable power controller (APC) and multi-turn pot.

Linear Temperature Programmer—This programmer is completely electronic with no gears, motor or clutch. It programs at 10 precise rates. A matrix plug permits any additional rates.

Single Channel Electrometer—This high impedance electrometer used with single ionization detectors features 100% feedback, decade and binary attenuation and buckout control.

Two Channel Electrometer—This electrometer, with flame and electron capture combination, is actually two electrometers with one common power supply. It features 100% feedback and buckout on each channel.

Bridge-Power Supply—This 12 or 20 volt solid-state bridge and power supply module is used in conjunction with 4-filament T.C. detectors. It is interchangeable in the Hy-Fl$_2$, 202 or 1520.

For accurate measurement of pH *...the*

RADIOMETER pH Meter 22

Included in the complete line of famous Danish RADIOMETER Electro-chemical instruments is the pHM 22. This model is a-c line operated and designed for general laboratory use inclusive of electrometric titrations.

Features

- Exceptional stability — no zero drift
- Large mirror scale spreads 14 pH over 11 inches
- Accessory biological meter 6-8 pH on a 6.4" scale
- Accuracy .01 to .05 pH with reproducibility down .002 pH
- 10 Millivolt ranges
- Accurate temperature compensation
- Will perform measurements on grounded media
- Will perform Dead Stop End Point titrations
- Full range of standard and special type electrodes

Applications

- pH determinations and millivolt measurements in the laboratory
- Continuous pH determinations or millivolt measurements
- Acid/base, redox or other potentiometric titrations
- Dead-stop end-point titrations

Descriptive literature on request.

ALSO AVAILABLE

PHA 630 P Scale Expander: Expands any selected 1.4 pH zone up to full scale proportions — nearly 6 times scale expansion.

PHA 621 External Meter: Presents on a full 7" mirrored scale, only the biological range of 6 to 8 pH.

sensitivity is low at high pressures, where the mean-free-path is small, and also at very low pressures, where the heat losses by conductance approach those resulting from radiation. Output is linear only over a small portion of the entire usable range, and the magnitude of the output is dependent upon the thermal conductivity of the particular gas being measured (Fig. 31). Thus, commercially available gages are usually calibrated with respect to dry air and require recalibration for other gases.

Basically, a thermal gage consists of a heated surface and a temperature-sensing device. Depending upon how the temperature-sensing is accomplished, the thermal gage is either a thermocouple-type or a resistance-type.

Thermocouple Gage. The simplest thermocouple gage is made by welding a thermocouple to the center of a wire which is heated. with constant energy-input, by means of direct current. Sensitivity may be increased by using a thermopile in place of the single thermocouple or by amplification of the thermocouple output. In either case, increased stability of energy-input to the heated wire is necessary.

Figure 33. Consolidated Vacuum thermocouple gage-tube.

Commercial thermocouple gages are available from many companies (Consolidated Vacuum Corp., Rochester, New York; NRC Equipment Corp., Newton Highlands 61, Massachusetts; F. J. Stokes, Corp., Philadelphia 20, Pennsylvania; The Fredericks Co., Bethayres, Pennsylvania; Elion Instruments, Inc., Burlington, New Jersey; General Electric Co., Schenectady, New York; Hastings-Raydist, Inc., Hampton, Virginia; Arthur F. Smith, Inc., Rochester 4, New York). These generally cover the range, 1–1000 microns (10^{-3}–1 mm Hg). Gage tubes are available from the above manufacturers for replacement when needed. Those of a given manufacturer are usually interchangeable without recalibration, if the heating current is set at the value indi-

Now there are only two. You and your Beckman Sales Engineer. He's one of 83 who now serve your analytical instrument needs directly. What does this mean to you? It means that when you talk to him, you're talking to a Beckman man—employed by Beckman, trained by Beckman, a Beckman Instrument Engineer. He doesn't just sell instruments, he works with the men who design and develop them. He's a jack-of-one-trade. An instrument man. Now meet him face to face.

Production Superintendent Carl W. Yost, B.S. Chemical Engineering, U. of Alabama, is now supervising Glycols and Polyols Production, Organics Division.

Assistant to Vice President Thomas E. Watson, B.A., Earlham College, is currently helping to run Brass Sales, Metals Division.

Senior Research Scientist Malcolm H. Von Saltza, Ph.D., U. of Wisconsin, is currently working at the Squibb Institute for Medical Research, Squibb Division.

They started with Olin 5 years ago.

These men, and a great many of their colleagues, have come a long way in 5 years. And they can expect to go a great deal further. Because at Olin, how well a man does depends entirely on his own character and abilities, not on age or politics or length of company service. (That's one of the reasons these men and others came to Olin in the first place.)

These men think a great deal; they wonder, they explore, they try. When they succeed, they're rewarded. When an idea doesn't pan out, they're encouraged to try and try again. Because here at Olin we believe that trial and failure are integral parts of every important success.

These are the kind of men we need, and we're more than willing to go a long way to get them. If you're our kind of man, the same goes for you. Can we talk about it? Say when.

Call or write Mr. Monte H. Jacoby, College Relations Officer, Olin, 460 Park Ave., New York 22, N.Y.

cated on the tube. Some of the companies supply glass, as well as metal, tubes. The readout device can be a simple microammeter of low resistance. Portable models use a 1.5-v dry-cell to supply the heating current, which may be read on the microammeter by use of a scale-multiplier shunt.

Consolidated Vacuum Corporation manufactures several models, one of which is shown in Figure 32. It is powered by a single "D" flashlight battery. The metal gage-tube is shown in Figure 33; it uses Cupron and Chromel P for the thermocouple junction. Line-operated models are available for single-or multichannel operation as well as with relay control.

Several models are also available from NRC Equipment Corporation. Some of them are provided with recorder output-terminals; others are suitable for pressure-control. The Model 521 Thermocouple Gage Tube consists of a combination heater and thermocouple, which is shaped like a cross. It is made by welding the midpoints of two very thin wires, one of Advance and the other of Nichrome. The four ends are then welded to the base of a standard octal tube. This construction results in high shock-resistance and very fast response. A typical gage tube is shown in Figure 34.

Figure 34. NRC thermocouple gage-tube.

The Stokes Vacuum Gage (Electrical Type) is available in three ranges, 0–100, 0–1000, and 0–20,000 microns, and with recorder or relay output-terminals (Fig. 35). The sensing element is a noble-metal thermopile which is heated by a constant ac, while the cold junctions are maintained at ambient temperature by heavy copper mounting-studs. Thus, the heated surface and the temperature-sensing device are combined into one.

The Elion Vacuum Gage, Model DVG-6, is available as a single-or multi-position unit, in cabinet or relay-rack mounting. It uses the Elion DVT-6, matched thermocouple-gage tube, which is of the noble-metal thermopile type. Despite rugged construction that reduces damage from vibration, the elements are so fine as to maintain the thermal time-constant below 0.06 sec.

From S/P—A trio of convenience items for your laboratory's

downs and . . . ups and downs . . . and ups

downs—Removing Dewar flasks or other apparatus from support rods is a convenient one-hand operation. Simply hold flask, release lever and VacRac nylon-fiberglas plate swings down out of the way. No. F4515—4″ x 4″ platform, 6″ support rod (without clamps) . . . $14.50. *ups and downs*—Raising and lowering laboratory apparatus is simple, sure with the S/P Roto-Lift support. Made of nickel-plated steel; cylindrical design distributes weight so capacity is almost limitless. Real simplicity . . . just loosen handle, set unit at desired height, tighten handle to lock in position. Adjusts from 2¾″ to 4¼″; top diameter of 3″. No. S9310 . . . $10.00. *ups*—Temperatures rise quickly with the S/P Flask Heater (you can boil 600 ml of water in less than 10 minutes)—concentrates heat where it's needed. No. H1540—dimensions: 6″ x 6″ x 6½″; 115 volts AC . . . $32.00. To take care of your ups and downs, order these items today.

belong in NEW KIMAX®

Super-Strength Beakers

An accident at the crucial point could mean lost time. Lost effort. Now Kimble has strengthened the conventional beaker to insure against this costly loss. You can expect new Kimax Super-Strength Beakers to last 300% longer than the ordinary type. Their longer life, greater accuracy comes from the improvements shown on the right.

Kimax Super-Strength Beakers are available in five sizes. Compare. You'll see how—good as conventional beakers are—the new ones from Kimble give you even more value with longer glass life at a competitive price. Orders can be assorted with those for other Kimax Laboratory Glassware to obtain maximum discounts available from most dealers.

EXPERIENCE AND CRAFTSMANSHIP
PUT QUALITY IN YOUR OHAUS BALANCE!

Yes, it took years of experience to produce this superior OHAUS CENT-O-GRAM balance and it's obvious at a glance. Capacities up to 311 grams are possible because of the inclusion of self-storing attachment weights. Sensitive to .01 gram, this balance boasts built-in speed with its convenient Rapid Action Balance Arrest and Recessed Threaded Zero Adjustment. Corrosion doesn't bother this balance either since Stainless Steel and Epoxy Enamel Finishes are used throughout. Tiered Beams, Relief Etched Graduations, Spirit Level, Adjustable Recessed Leveling Feet, True Sliding Type Poise, and Double Hook for Specific Gravity Determinations are only a few of the features experience has taught us you demand in a precision laboratory instrument. Add all this to the famous OHAUS Self-aligning Agate Bearings and precision ground Special Steel Knives and we are confident you will also choose OHAUS . . .

the LEADER who INVITES COMPARISON!

Figure 35.

Resistance Gage. In the resistance gage (Pirani gage), temperature is sensed by observing the resistance change of a metal or semiconductor, which usually forms part of a Wheatstone bridge. The bridge is excited by a voltage sufficiently large to cause self-heating of the resistance element, so that no auxilliary heated-surface is required. Ambient-temperature compensation can be obtained by using a second sensing-resistor, sealed in a good vacuum, in an adjacent arm of the bridge. The readout consists either of the bridge-unbalance voltage or of the current necessary to restore the bridge to balance. The latter may be accomplished automatically by means of a feedback network or servo system. These gages generally cover the range, 1–1000 microns.

Figure 36. Consolidated Vacuum Pirani gage.

Consolidated Vacuum Corporation supplies several models, including the unbalanced-bridge type as well as the self-balancing-bridge type. They are available for single or multiple-station operation as well as for recording and control (Fig. 36), with sensing tubes made of either metal or glass. Other Pirani gages are available from several sources: NRC Equipment Corporation; Hastings-Raydist, Inc.; Jelrus (available from Wilkens-Anderson Co., Chicago 56, Illinois).

The final section of this article will deal with ionization gages. A bibliography will be included with that section.

BARNSTEAD'S NEWEST

HOSE NIPPLE TYPE WATER DEMINERALIZER CARTRIDGE FOR SCHOOL AND COLLEGE LABS

1. Provides low cost deionized water for small volume or infrequent users.
2. No equipment expense. 30% to 50% lower cost per gallon than with other brands.
3. Hose nipples on both ends for easy connection to faucet and collection vessel with ordinary laboratory tubing. No tools needed.
4. Can be used on closed systems under pressure up to 25 psig. Flow rates up to twenty gallons per hour.
5. Complete line includes Oxygen Removal, Organic Removal and other special types.
6. No meter or electrical connection needed. Clamps onto Lab Stand or bracket is available for wall mounting.
7. Its low cost makes it possible to produce deionized water in every school and college laboratory.

WRITE: Bulletin #190 describes Barnstead's complete line of Hose Nipple Cartridges. Yours for the asking. No obligation.

The Case of the Meandering ML's

In the vicinity of many research laboratories, small organic solutions are being mysteriously lost, daily. They are placed in small flasks, heated, and then . . . they vanish. Chemists patiently wait for their meandering ml's to show up. Sometimes a few straggle into fraction cutters, but most of them escape. The M.O. is always the same. Our job . . . find them.

Acting on a tip from Dr. Raymond Firestone at Merck & Co., Rahway, we went to work on our new K-28480 Bantam-ware Short Path Fractionator. Make the column about an inch long and let the thermometer bulb and stem serve as a packing, he said. Construct the condenser and vacuum connection in two inches, total length. Use only one joint on the fraction cutter but design it so that pipettes can be inserted to the bottom of any of the four receivers. Then, tilt the whole assembly so that drops fall from the drip tip ₮ 14/20 joint into one of the four receivers without unnecessary wetting. But nothing is vertically aligned, we pleaded. I know, he said. In desperation, we tried it.

We're happy to report that most of the meandering ml's now show up as product. The case is closed. Sequel: K-28480 has been added to the line because it fits in with the whole Bantam-ware concept. Very compact, low hold-up . . . functional.

Incidentally, that little rectangular box in the photo is our new Un-A-Watt voltage controller. It occupies 1/15th the space and weighs only 1/10th as much as a conventional coil transformer. It is custom made for Bantam-ware heating mantles with 0-60 Volt range, sparkless operation, removable support rod and high sensitivity. It fits in with the Bantam-ware concept also.

Bantam-ware Kits and hundreds of individual pieces are described in Catalog BW-2. Write for it today.

teacher's pet

A Gas Chromatograph for use as a teaching device must possess two almost opposite qualities: low cost and high performance. ▪ The $995.00 price of F & M's new Model 700-00 Gas Chromatograph clearly meets the first requirement. But this in itself is no great accomplishment: others have done it. The difference is that the Model 700-00 is a high-performance dual column thermal conductivity instrument with many features that enhance its usefulness in teaching modern techniques of instrumental analysis: high temperature operation, regulated voltage supply for oven and detector heaters, manual temperature programming, easy column and oven accessibility and a modular design to permit the addition of attachments as the need arises and the budget permits. ▪ Write for full details on the Model 700-00, a rugged instrument that takes student abuse in stride, and carries the standard F & M full-service one year warranty. F & M Scientific Corporation, Route 41 and Starr Road, Avondale, Pennsylvania, tel. 215-268-2281. European subsidiary: F & M Scientific Europa N. V., Leidsestraat 67, Amsterdam, The Netherlands.

Chem Ed

Out of the EDITOR'S BASKET

Edited by William G. Kessel

When writing for additional information about new products or for new literature, your inquiry will receive prompt attention if you write on your firm or Institution letterhead and mention the Journal of Chemical Education and the date of the particular issue. Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ A family of three new compact neutron generators providing high neutron yield at low cost, and designed for either steady or pulsed operation, have been introduced by SAMES (Societe Anonyme de Machines Electrostatiques) of Grenoble, France. Further details may be obtained by writing SAMES USA, Inc., 269 Commercial Ave., Palisades Park, New Jersey.

▶ The Blood Gas Accessory is a sample conditioner used in combination with the Beckman GC-2A Gas Chromatograph. Instrument performance will permit a 4-min., standard run analysis of oxygen, nitrogen, carbon monoxide, and carbon dioxide in a blood sample. Write the Technical Information Section, Beckman Scientific and Process Instruments Div., 2500 Harbor Blvd., Fullerton, California for *Bulletin 7019*.

▶ Westronics, Inc., 3605 McCart St., Fort Worth 10, Texas, announces the availability of their new laboratory strip chart recorder Model LS11A, which was designed exclusively for laboratory and basic research personnel. Ask for *Data Sheet 273*.

▶ A unique deal survey instrument for practically the cost of a standard alpha or neutron device is announced by Physics International, 2229 Fourth St., Berkeley 10, California. The PI Master Survey Instrument normally functions as a large area alpha instrument, but also features a directly interchangeable probe that functions as either a thermal or fast neutron detector.

▶ To permit the rapid and reproducible analysis of pyrolysis products by gas chromatography, F & M Scientific Corp. of Avondale, Pennsylvania has introduced a new dual probe pyrolysis unit, the Model 80. The device permits the pyrolysis of non-volatile substances containing traces of organic materials, directly in the injection port of the gas chromatograph.

▶ Prepkromatic, a unique advance in gas chromatographic instrumentation has been announced by Nester/Faust Mfg. Corp., 2401 Ogletown Rd., Newark, Delaware. This versatile instrument provides rapid, automatic injection, separation and collection of pure chromatographic fractions on a repetitive basis.

▶ Sturdilite Products, Inc., 3001 Palmolive Bldg., Chicago 11, Illinois, announces a copper shielded laminated counter top for use in areas where shielding or radio frequency interference problems are present.

▶ The RS5-2 salinometer just announced by Industrial Instruments, 89 Commerce Rd., Cedar Grove, New Jersey, features an inductive cell that operates without electrodes and eliminates all electrode maintenance problems. The instrument provides direct linear readout and permits salinity, temperature and conductivity measurements to be made to depths of 400 feet by simply lowering the electrodeless cell.

▶ Bel-Art Products, Pequannock, New Jersey, offers heavy walled polyethylene trays with welded construction that are rigid, tough, unbreakable and impervious to strong acids, alkalies, and some solvents.

▶ Scientific Products, 1210 Leon Place, Evanston, Illinois, offers a completely disposable sterile polyethylene bag for transporting or storing liquid or solid samples. Pull-tab opening eliminates contamination from fingers.

Three reasons you're better off buying through a PYREX® *brand labware dealer*

Number one is his knowledge. He knows your lab and he knows the new, blue PYREX brand labware Catalog LG-3.

That's why he can help you choose the specific labware item that will handle your tasks best. He's got "best buy" recommendations in more than 20 labware categories—from beakers to tubes—and he can offer special-application suggestions, too.

And there's greater convenience. A telephone call across town starts things moving fast for you.

There's a full inventory for you to order against, too. You can expect off-the-shelf delivery from your dealer, because that's his business.

You can count on the companies that distribute our labware to give you helpful, personal, convenient service, coupled with fast deliveries.

Your Corning dealer is a good man to do business with. We know. Laboratory Glassware Dept., Corning Glass Works, 7710 Crystal St., Corning, New York.

▸ The Reichert "Visopan," a complete micro-projector combining a microscope, an illuminating system, and a projection screen into one compact unit, can now also be equipped for photomicrography with 4 × 5 inch Graflok back and for application of the standard Polaroid Land Camera back. For complete particulars write to: William J. Hacker & Co., Inc., P.O. Box 646, West Caldwell, New Jersey.

▸ Economical time and count print-out for automatic sample changer systems is offered by Nuclear-Chicago's new Series 8700 instruments. They combine a fast decade scaler, an electronic timer, regulated high voltage supply, and sample changer programming facilities in a single, compact model. Solid state circuitry is used throughout. For complete specifications write to Nuclear-Chicago Corp., 359 E. Howard Ave., Des Plaines, Illinois.

▸ Telewave Laboratories, Inc., 43-20 34th St., Long Island City 1, New York, introduces a variable speed chopper for infrared, ultraviolet, and visible light. It lends itself for use in prototype development, test instruments, transmitter and receiving systems, and general-purpose laboratory applications.

▸ A new nuclear counting system, the Multi/Matic MM560, for rapid, accurate analysis of radioactive materials has been introduced by Tracerlab, 1601 Trapelo Rd., Waltham 54, Massachusetts. The Multi/Matic MM560 counting system uses interchangeable detector heads for assay of solid samples in which alpha, beta, or gamma radiation may be present in varying amounts.

▸ Plugs of "Teflon" TFE provide vacuum-tight seals yet smooth-gliding action in three new plastic stopcocks developed for laboratory use by The Nalge Co., Inc., 75 Panorama Creek Drive, Rochester 25, New York.

▸ New plastic coated round bottom flask rings that abolish the need for old fashioned cork rings has been introduced by Penn-Chemical Corp., 232-38 N. Marshall St., Lancaster, Pennsylvania.

▸ The Gyra Model E-307 Electrometer for improved performance, accurate zero, greater stability and faster response, is offered by Gyra Electronics Corp., P.O. Box 184, La Grange, Illinois.

▸ Scientific Glass Apparatus Co., Inc., Bloomfield, New Jersey, announces the development of a new manometer originally designed for use by students in introductory organic chemistry, but which is also suitable for measuring pressures in the 0–140 mm range in any laboratory.

▸ Recognizing a need for an increased degree of precision in measuring the vis-

INTERFEROMETRIC CONTROL . . . KEY TO QUALITY LEADERSHIP

for Bausch & Lomb

Certified Precision Diffraction Gratings

EVERY STEP OF THE WAY . . . the testing of master grating blanks, coatings, groove shapes, diamond and grating carriage motion, and quality of masters and replicas . . . is under the most rigid INTERFEROMETRIC control. You are assured of the highest precision standards and finest quality gratings you can buy. Since 1950, reliance on INTERFEROMETRIC control has been the key to the high resolving power, low ghosts and high efficiency which have made Bausch & Lomb Diffraction Gratings world famous . . . and preferred by all major manufacturers of spectroscopic instruments.

There are 672 different sizes and types of plane reflectance, transmission and concave gratings that cover a range of wavelengths from 10A (x-rays) to 10^7A (far infrared). We can also produce special types for your unusual requirements. Any size up to 200 x 350mm (8" x 14") is currently available. (Again, larger sizes can be obtained on special order.)

Our subterranean laboratory, built within layers of solid rock, offers stability, cleanliness and a unique capacity to supply gratings in even large quantities . . . within reasonable delivery requirements.

Thirteen years of pioneering experience in developing and supplying gratings to astronomers, spectroscopists, instrument manufacturers, and other scientists has given Bausch & Lomb engineers the extensive knowledge and unequaled know-how that can assist you with your grating problems. Write to Bausch & Lomb Incorporated, 66146 Bausch Street, Rochester 2, N. Y., for the new Catalog D-261 for prices, uses, characteristics and details on the theory and mechanics of diffraction gratings . . . it's the most comprehensive gratings catalog available anywhere.

BAUSCH & LOMB

In Canada, write Bausch & Lomb Optical Co., Ltd., Dept. 661, Scientific Instrument Division, 16 Grosvenor Street, Toronto 5, Canada.

cosity of fluids, Ferranti Electric, Inc., Industrial Park No. 1, Plainview, Long Island, New York, made available a new electronic viscometer a few years ago. The company now announces that four distinct improvements have been made in the viscometer, which analyzes fluid substances by placing a small sample between a rotating metal cone and a stationary flat plate.

▶ Barnstead Still and Sterilizer Co., Lanesville Terrace, Boston 31, Massachusetts, reports that its steam heated still with new feedback purifier eliminates water Still cleaning, provides distilled water of higher purity, and now incorporates two new features which insure efficiency of operation.

▶ Instrument and Communications, Inc., 33 Danbury Rd., Wilton, Connecticut, offer a new, inexpensive, all solid state, recorder accessory which provides 10:1 gain in sensitivity for any potentiometric recorder. It is called the Variable Recorder Amplifier.

▶ A new X-Band electron paramagnetic resonance spectrometer of extreme sensitivity is now available from Alpha Scientific Laboratories, P.O. Box 333, Berkeley, California. This unit is an addition to the standard 340 megacycle and 30 to 60 megacycle EPR units which have been available.

▶ A new portable electrophoretic instrument capable of quantitative and qualitative biomedical, chemical, and pharmaceutical analyses often unavailable through other techniques has been announced by Perkin-Elmer Corp., Norwalk, Connecticut. Designated the Model 238 Tiselius electrophoresis apparatus, the instrument uses a method widely applicable to analysis of protein mixtures and fractional purifications.

▶ Scientific Machine & Supply Co. of Middlesex, New Jersey has developed an adjustable thermometer seal that eliminates the need for multi-laboratory equipment. The new seal will fit any laboratory flask and utilizes any conventional thermometer.

▶ A new recording spectropolarimeter, designed for the precise, automatic recording of optical rotatory dispersion over the wave-length range from below 1900–6000 Å is being introduced by Applied Physics Corp., 2724 S. Peck Rd., Monrovia, California.

▶ Both automatic printed readout and variable function conversion, features usually associated only with much larger and more expensive computers, are performed by Datascribe, a new bench-top size, analog to digital converter now being produced by Research Specialties Co., 200 S. Garrard Blvd., Richmond, California, for general laboratory use.

▸ Designed to produce intense homogeneous fields over a large volume, Alpha's new aluminum strip wound solenoid coils provide an efficient magnetic field suitable for many requirements. This solenoid is one of a standard series of solenoid coils produced by Alpha, which are capable of providing fields up to 20 kilogauss. For details write Alpha Scientific Labs., P.O. Box 333, Berkeley 1, California.

▸ The labware industry's first plastic separatory funnel is announced by The Nalge Co., Inc., 75 Panorama Creek Dr., Rochester 25, New York. Available in a 500 ml. Squibb pear shape design, the new Nalgene® separatory funnel is molded of unbreakable polypropylene featuring unusual clarity.

New Literature

● A new brochure describing four models of explosion-proof refrigerators and freezers is now available from Kelmore, Inc., 599 Springfield Ave., Newark 3, New Jersey.

● The Amersil Quartz Div. of Engelhard Industries, Inc., 75 Austin St., Newark 14, New Jersey, has published a new *Data File* on quartz glass bi-distillation apparatus. The bi-distillation apparatus described prepares water of 0.55 to 0.9 $\times$ 10^{-6} (Siemens/cm) in a single operation as two distillation stages are incorporated in a single closed system.

● The Model 154D vapor fractometer, basic instrument in the Perkin-Elmer gas chromatography line, is described in a new 12-page brochure. Designed for industrial or research analyses, the Model 154 D features the latest advances in gas chromatographic sampling, separation and detection techniques. Copies of the booklet are available on request from Instrument Div., Perkin-Elmer Corp., Main Ave., Norwalk, Connecticut.

● Copies of a new laboratory hardware brochure are available from Central Scientific Co., 1700 W. Irving Park Road, Chicago 13, Illinois.

● A descriptive flyer and sample of Carter Products Co.'s flexible rubber magnet may be obtained from Carter Products Co., P.O. Box 1924, Columbus 16, Ohio.

● A new brochure is available on safety pipetters describing "Clinac" mechanical pipetters in micro and standard sizes and the "Pumpett" automatic pipette control from La Pine Scientific Co., 6001 S. Knox Ave., Chicago 29, Illinois.

● Cahn Instrument Co., 15505 Minnesota Ave., Paramount, California offers new descriptive literature on the "*Cahn R. G. Electro-balance.*"

(*Continued on page A806*)

Ferro-electric boundaries in barium titanate film 70,000X ▸

STUDY 39% THICKER SPECIMENS AT HIGH RESOLUTION WITH THE JEM-150 ELECTRON MICROSCOPE For the first time, a high-voltage, high-resolution electron microscope is commercially available in the United States and Canada. It's the JEM-150 from Fisher—newest in the distinguished JEMscope line. Its 150-KV, one-stage electron accelerator gives metallurgists and solid-state physicists 39% greater specimen penetration than the best 100-KV instrument. Guaranteed resolution: 10 A. Continuously variable magnification: 600X to 200,000X. Attachments let you manipulate, modify specimens while in the microscope. Basic price: $68,099 duty-paid; $58,595 duty-free. Available through Fisher Financing Plan. **More facts** about the JEM-150 in free Bulletin FS-240. Write Fisher Scientific Company, 109 Fisher Building, Pittsburgh 19, Pa.

Bounce a 3-lb. ball from 9 feet. **DURCON® LABORATORY SINKS** can take it. Durco uses the 3-lb. ball drop test as a quality control. This impact test is far greater than that encountered in normal laboratory usage.

The strength and durability of DURCON, along with its excellent corrosion resistance, are the results of a special epoxy resin formulation of Durco.

DURCON sinks also give you much more in other areas: low cost, lightweight, easy to install, complete drainage and easy cleaning because of dished bottom and coved corners; lasting beauty because DURCON doesn't stain or corrode and greater design flexibility because of a wide selection of shapes and sizes. Write for free bulletin PF/5e.

FILTRATION CHART

for use in chemical analysis

relative retention values

OF S&S ANALYTICAL FILTER PAPERS

Our laboratory pioneered new methods for the quantitative evaluation of filter papers which have proved of considerable help to the chemist in the standardization of their speed and retention ranges.

This retention method, employing a finely divided dispersion, assigns numerical test group values to S & S filter papers — for equal precision with very fast, loose textured grades and sheets of greatest density.

The wide range of this novel retention scale, and the diversity of S & S filter papers, are represented graphically on the sedimentation cylinder. The graphic representation is illustrative of the general range of retention of S & S Analytical Filter Papers. For additional copies of the S & S Filtration Chart, address Dept. JCE-310.

Bronwill brings you Godfrey Stereomodels

Can you match these Stereomodels with their correct names? See bottom of page.

SEE SKELETAL STRUCTURE...ACTUALLY MEASURE INTERNUCLEAR DISTANCES

GODFREY STEREOMODELS are of tremendous importance to teachers, students and research chemists. They present chemical relationships better than ever before possible. You can see skeletal structure . . . how atoms are linked . . . whether they are stable . . . and why. You can even measure internuclear distances with remarkable accuracy . . . a precise, 250,000,000× magnification of all elements is ingeniously maintained (2.5cm = 1Å). Bond angles are correct, too. Elements are all vividly, solidly and permanently colored throughout . . . and virtually unbreakable, too! Free rotation about single bonds is demonstrable . . . yet structures will remain locked in any preset position. Boat or chair conformation of cyclohexane show their natural stability . . . even intermediate twist conformations can be fixed in position for handling and measurement.

The basic kit is supplied, at no extra charge, with a large variety of structural components . . . olefinic and aromatic double bonds, acetylenic triple bonds, the benzene ring, amide and nitrile groups, as well as tetrahedral and trigonal carbon and nitrogen, digonal oxygen and sulfur, hydrogen and the halogens . . . at a price, one-third of any competitive units. No tools are required for any assembly . . . simple, quick, hand connections only. Connector tubes have positive, snap-lock connections, with built-in torsional friction. Large, complex models (synthetic polymers, proteins, polysaccharides) can be assembled and handled without inadvertent disruption.

STEREOMODELS IN TOP PHOTO: A. Methylacetylene; B. α Phenoxyethyl Penicillin; C. *cis* Decalin; D. Bicyclo [2,1,1,$0^{5,6}$] hexane-5 (N-t-butyl) carboxamide; E. 6-Trifluoromethyl -7-sulfamyl-3,4-dihydro-1,2,4-benzothiadiazine 1,1-dioxide.

It would have been easier if they were visible in their full, identifying colors. Write today for full color brochure.

BRONWILL No. 90, GODFREY STEREOMODELS. . . . Complete Kit, $49.95 each (lots of 12—$45.00, lots of 24—$40.00)

NEW from MANOSTAT

DIGI-PET

NEWLY DESIGNED PUSH-BUTTON RESET COUNTER WITH FOUR-DIGIT DIRECT READOUT GIVES ACCURACY AND SENSITIVITY NEVER BEFORE POSSIBLE!

No Calculations—new digital counter provides quick, accurate *direct reading* of volume dispensed. *Sensitivity: .01%! Accuracy: up to 0.1% of dispensed volume!* You can perform repeated titrations with a single filling. ■ **Other Digi-Pet Features**—unique push-button action lets you dispense and reset *with one hand.* Counter is designed for easy grip and comfortable hand operation. Comes complete with adapters for clamp mounting. Pipet models are available with interchangeable tips: straight, luer or right angle bend. Buret models for ultramicro work come complete with mercury and metal stand. Digi-Pet is available in 0.01 ml, 0.1 ml, 1.0 ml and 10.0 ml sizes—all at amazingly modest prices: from **$139.50** each.

See your local laboratory supply dealer.

Write for descriptive bulletin.

processing laboratories are illustrated in a new 68 page catalogue, *LG3-Blt.* Write for a copy to the Denver Equipment Co., 1400 17th St., Denver 17, Colorado.

● The Lab-Crest Scientific Div. of Fischer & Porter Co., 574 Jacksonville Rd., Warminster, Pennsylvania, announces the publication of a new complete price book on its line of laboratory equipment and glassware.

● *Union Carbide's Research and Development Capabilities* are described in a new folder. Copies may be obtained by writing to Department 43, Union Carbide Corp., 270 Park Ave., New York 17, N. Y.

● The Edmund Scientific Company's new catalogue *No. 635,* featuring thousands of unusual and hard-to get industrial and scientific items, is now available free on request. Write Edmund Scientific Co., Barrington, New Jersey for a copy.

New Chemicals

◇ W. H. Curtin & Co., P.O. Box 1546, Houston 1, Texas introduced a new aid for gas chromatographers, a series of inexpensive packing kits for GC columns. These helpful kits will assist the laboratory worker to quickly determine which chromatographic column best suits their individual requirements.

◇ Three new radiochemicals for use as chromatography standards or in atherosclerosis nutritional and fat metabolism studies are immediately available in liquid form from Tracerlab, 1601 Trapelo Road, Waltham 54, Massachusetts. Methyl Linoleate-1-C^{14} (*Catalogue L4-86*), Methyl Oleate-1-C^{14} (*Catalogue L4.84*), and Methyl Stearate—1-C^{14} (*Catalogue L4-83*) are also available.

Miscellany

★ Bell Telephone Laboratories has announced the availability of two new college science films, one in the field of physics and the other in physical chemistry. The films entitled "Principles of the Optical Maser" and "Physical Chemistry of Polymers," were prepared at Bell Laboratories under the direction of scientists who are acknowledged authorities in their fields. Both films are available on free loan from local Bell Telephone business offices throughout the country.

★ The story of the Muller Field Ion Microscope, with which scientists are able to observe the atomic structure of matter for the first time, is told in a new 16mm film just released by Cenco Educational Films. Entitled "Eye for Tomorrow," the 15-min black and white production traces the development of the Field Ion Microscope from its conception by Dr. Erwin Muller, of the Pennsylvania State University, until it became a working instrument available to the world's scientists just a year ago. With a possible magnification of over 3,000,000 times and a resolution of better than three Angstroms, the Field Ion Microscope promises to be one of the most significant scientific instrument development of this decade. For further information regarding the film "Eye for Tomorrow," write for Booklet 509 from Cenco Educational Films, a division of Cenco Instruments Corp., 1700 Irving Park Rd., Chicago 13, Illinois.

★ The 1963 Eastern Analytical Symposium will be held at the Statler Hilton Hotel in New York City on November 13, 14, and 15, 1963. The purpose of this announcement is to present the program of the meeting which is being sponsored by the Analytical Groups (ACS) of the New York and North Jersey Section, four sections of the Society for Applied Spectroscopy (New York, Delaware Valley, New England, and Baltimore-Washington), and the American Microchemical Society.

The meeting will consist of a series of 3-hr symposia of invited papers of extended length by experts in a number of fields of interest to instrumental analysts, chemists, and spectroscopists. The emphasis will be on recent developments in these specialties. The exhibition will consist of 90 manufacturers of scientific apparatus and supplies. Contact the General Chairman—J. F. Cosgrove, General Telephone & Electronics Labs or Program Chairman—H. C. Mattraw, Sperry Rand Research Center for details.

Semi-Micro Chemistry

New Film Shows Better Way To Teach High School Laboratory Chemistry

Sound slidefilm points up learning, teaching and economic advantages of miniature system

CHICAGO: The inherent advantages of the semi-micro method of laboratory chemistry are depicted in a new slidefilm, full color with sound, sponsored by Wilkens-Anderson Company, Chicago.

The film, shot in actual high school chemistry classes, discusses semi-micro from three viewpoints: the student's, the teacher's and the school administrator's.

Compares Semi-Micro and Macro

In order to more vividly portray the benefits of the semi-micro method, a dramatic classroom comparison with macro is used. The film does not dwell on the comparison alone, but moves quickly on to such student and teacher advantages as more experiments, accuracy, safety and greater individual attention.

Easy Conversion Stressed

In depicting the economic advantages of semi-micro, special attention is devoted to the ease of conversion and the fact that NO capital expenditure need be appropriated. Cost comparisons, savings on replacement costs and other features, of interest to both teacher and administrator, are discussed.

The filmstrip, priced at $14.95, is available on FREE loan to all science department heads, teachers and school board members. Write, stating school and position, to Wilkens-Anderson Co., 4525 West Division St., Chicago, Illinois.

ACT-O-MATIC™

DUAL-POSITION PROJECTOR

SETS THE STAGE INSTANTLY for vertical or horizontal science projection

Compare these features

- self-contained unit, needs no adapters or rebuilding for dual projection
- colorful "live action" projection always in sharpest focus
- continuous sequence from vertical to horizontal operation and back again
- constant, short focal length keeps instructor up front of the class
- exclusive triple condenser system for high light intensity and even illumination
- exceptional visibility for as many as 300 students

Act-O-Matic gives every student a front row seat and keeps the instructor at the head of his class for all science demonstrations. "Live action" projections, instantly transferred from vertical to horizontal positions and back to vertical, maintain a lively unbroken sequence to hold every student's interest and make every lecture a simple project for the instructor. **Only** Act-O-Matic can give you a completely integrated projection system to meet all of the "TOPS" requirements. **Only** Act-O-Matic can assure you of the full power and versatility to do the whole science demonstration job . . . without costly adjustments or makeshift adaptations. **Only** Act-O-Matic provides the most complete line of accessories and devices designed to do a full science projection series.

WRITE OR CALL TODAY FOR BULLETIN AOM62

WORLD FAMOUS DESIGNERS AND MANUFACTURERS OF EDUCATIONAL SCIENCE FURNITURE

vertical

Demonstrations projected involving liquids, heating and cooling, gravitation, gas generation, and devices such as electrolysis cells, flasks, electroscopes and various measuring instruments.

horizontal

Projects transparencies up to 5" x 5", petri dishes, culture dishes and watch glasses. Also action notes and diagrams as rapidly as they are written or set on the projection stage in prepared form.

Note: Figure SD-18 Cryophorus for Dem. 88 in the September issue appears on the next page.

2. PHYSICAL PROPERTIES OF WATER (Continued)

Humidity

Dem. 95—Humidity Indicator

To show: Moisture is in the air, evidenced by the color change of a cobalt salt.

Materials: 5 × 1-in. strip of clear photographic film (or clear plastic film dipped into a thick gelatin solution and dried), $CoCl_2$, isopropyl alcohol, cell C-2.

Preparation: Soak the plastic strip in conc. $CoCl_2$-aq. Heat gently to dry to a blue color. Store dry in a stoppered bottle.

Procedure: (*a*) Lower the blue strip into the chambers of C-2 in (1) dry air, or isopropyl alcohol and (2) water. (*b*) Hold a strip tightly in the palm of the hand, or breathe on the strip. Project.

Observations: (*a*) the $CoCl_2$ turns pink in water, blue in dry air or isopropyl alcohol. (*b*) Moisture from the hand or breath colors the blue strip pink; even the fingerprints can be seen projected.

Note: At this point show the class a "weather tell-tale" available in gift shops, usually a card with cloth colored by $CoCl_2$ which turns blue for fair (dry) weather and pink for rainy (wet) weather. Also show Drierite or silica gel desiccant which has been treated with $CoCl_2$ to show whether the absorbent is fresh (blue) or spent and unsuitable (pink).

Dem. 96—Wet-Dry Bulb Thermometer

To show: Relative humidity by contrasting the temperatures of wet and dry bulbs, the principle of a psychrometer.

Materials: Two 1-oz. square dropping bottles with rubber bulbs, 2 mm capillary tubing 6-in. long, food coloring, a piece of cloth about 4 × 1½ inches, rubber band.

Preparation: Cut the rubber stoppers half-off, and through them lead the capillary tubing bent into an inverted U-tube 3-in. long. Wrap one of the bottles in cloth and secure with the rubber band.

Procedure: Immerse both bottles in a trough of water for several minutes. Remove, wipe the unwrapped bottle dry. Place a drop of colored water in the capillary U-tube in the arm which will lead into the unwrapped bottle. Insert the U-tube in the bottles. Project.

Observation: Within a minute the cooling effect of the evaporation of water from the wet cloth will cause the colored liquid to move toward that bottle. (Noerdin)

Dem. 97—Bobby-Bird

To show: Evaporation of water causes contraction of air, and makes the Bobby-bird duck his head.

Materials: An all-glass Bobby-bird, available in some gift shops, the bird who continually bobs down his beak into a pan of water; plastic frame for the bird.

Preparation: See SD-19. The paint and feathers must be dissolved off the glass bird, acetone being a good solvent. Leave the cloth material on the bird's head. Make a base as shown in Figure SD-19, and pivot the bird so that he is just barely upright. A block at his head helps adjust him properly.

Procedure: Pour water over his head. Project. In a few minutes he will begin to duck down, then swing upright, repeating the cycle at minute intervals for some quarter of an hour.

Notes: 1. Explain how evaporation of water from the cloth head cools down the air inside the head; this creates a partial vacuum, and the liquid inside of the inner straight tube can be seen on the projector being sucked up toward the head. When sufficient liquid has reached the forward portion of the bird, the center of gravity has shifted sufficiently for the bird to duck downwards.

2. Call attention on the screen how the liquid in the head of the bird flows along the inner tube, and air from the tail transfers to the head during the return-to-upright movement.

3. It is unnecessary to have the head dip into a pool of water. Sufficient water can be placed on the head in one dunking to make the bird operate for many minutes. Of course if it ducks its head into a tank of water the process will continue indefinitely.

Aqueous Tension (Vapor Pressure of Water)

Dem. 98—Desiccation of Moist Air

To show: The drop in vapor pressure of water vapor in the presence of a desiccant.

Materials: Test tube connected via rubber tubing to a mercury-filled Mp-760 manometer; Drierite.

Procedure: Fill the test tube with *moist* air (breath), and connect to Mp-manometer. Project. Drop in a quarter tube-full of Drierite or other solid desiccant.

Observation: The pressure drops steadily as the water vapor is absorbed by the desiccant. (Ulery)

Dem. 99—Vapor Pressure of H_2O at Room Temperature

To show: A comparison of the vacuum achieved with an oil pump versus a water aspirator.

Materials: Oil pump, water aspirator, Mp-o with valve and 6 mm tube with serum cap in stopper, 2 ml hypodermic syringe.

Procedure: (*a*) Clean, and dry Mp-o thoroughly (this is important). Evacuate it, and shut valve. Project. Record level (or differences in levels) in the J-o manometer. Inject 0.5 ml H_2O. Record the new heights.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

(*b*) Fill the Mp-box half full of water, evacuate with (*1*) oil pump, (*2*) water aspirator. At the end of the latter operation admit air before turning off aspirator to avoid flooding Mp-o with water. Read new J-tube levels.

Observations: (*a*) The change in pressure is about 28 mm at room temperature of about 28°C. (*b*) The oil pump gives a near-zero reading; a good water aspirator gives a reading about 28 mm higher, corresponding to the vapor pressure of water at 28° C. (Ulery)

Dem. 100—Vapor Pressure of H_2O at Different Temperatures

To show: The change in vapor pressure of water as temperature is changed.

Materials: Mp-J-tube assembly, 5 × $1^3/_4$-in. transparent plastic trough, 2 ml syringe, 18 × 70 mm test tube with 2-hole stopper, 1-in. length of 6 mm tubing with rubber serum cap, fish-valve, 0–100°C. thermometer, vacuum source.

Preparation: Bore hole in base of valve and solder in it a $^1/_2$-in. length of $^1/_8$-in. brass tubing. In the 2-hole stopper insert this valve and also the 6 mm tubing with serum cap. Connect to J-tube assembly.

Procedure: Evacuate test tube-J-tube assembly, shut valve, remove from vacuum pump, and place in plastic trough on projector. Record pressure and temperature readings for (*a*) tube empty at room temperature, (*b*) tube with 2 ml of H_2O injected at room temperature, (*c*) ditto, with 2 ml more of H_2O injected, (*d*) with 4 ml H_2O and with entire assembly immersed in trough of ice-water, and (*e*) ditto, in water at 30 to 50°C.

Observation: Vapor pressures of H_2O at 1°, 26.2°, and 47.0°C. were 5.0, 28, and 79 mm respectively, within 5% of theoretical. (Ulery)

Dem. 101—Deliquescence

To show: The deliquescence of NaOH and $CaCl_2$.

Material: NaOH pellets, 4-mesh $CaCl_2$, microscope slides, horizontal projector or cell Ho.

Procedure: Place a NaOH pellet at one end of a microscope slide, and a lump of 4-mesh $CaCl_2$ at the other. Project for 15 min on a horizontal stage.

Observation: Puddles of solution form as the substances deliquesce. (Rolf)

Dem. 102—Deliquescence of $MgCl_2$

To show: The slow deliquescence of $MgCl_2$.

Materials: $MgCl_2$, test tube or vial fitting inside of Mp-o.

Proceedings: Half-fill the glass vial with a saturated solution of $MgCl_2$, or solid $MgCl_2$, and set in Mp-O quarter-full of water. Evacuate and shut the valve. Let stand. Project from day to day.

Observations: Water passes over into the tube containing the $MgCl_2$ as it deliquesces. The level of water rises in the $MgCl_2$ tube and falls in the outer Mp box over the following days.

Notes: 1. Mark the water level each week for a month.
2. A plastic inverted U-tube with saturated $MgCl_2$ in one limb and water in the other can be used. Or, a flat cell with two limbs connected by a passage-way. Hang up out-of-reach of the pupils so that it can be observed from day to day, but not disturbed or tilted.

NEW! QUICK! EASY!

Ultra Pure DISTILLED WATER

10 WITH THE CORNING ALL GLASS STILL

Important Features:

1. Completely constructed of inert materials, PYREX (R) BRAND components, VYCOR (R) brand immersion heater, new PYREX (R) brand 1:5 Teflon (R) plug stopcock; absence of heavy metal contaminants.
2. Complete visibility of all glass parts for case in troubleshooting.
3. Ultra-pure glass-distilled water, conductivity extremely low.
4. Easily drained and cleaned; parts easily replaced.
5. Produces Pyrogen Free water; tests conducted in accordance with U.S.P. XVI.
6. Flexible—capable of performing single distillation in one pass from tap water, yet quickly adaptable to operation as the second stage to a double distillation system.
7. Automatic operation. Thermostatic protection. of apparatus from overheating.
8. Includes electrical control box which reduces thermostat voltage to 12 volts, shuts off power to immersion heater if water drops below proper operating level.
9. Completely self-contained; all components necessary for operation are mounted within a painted steel cabinet.
10. Continuous removal of volatiles through well designed venting system.

ORDER NOW!

Cat. No. JC54685-Net weight—60 lbs. (including cabinet). Shipping weight approx. 120 lbs. 44" high, 17" wide, 12" deep. 220-250 Volts A.C., 15 amps..... Each $495.00

ACCESSORIES

Cat. No. JC54685A—Removable insulated Polyurethane jacket (for evaporator) for increased efficiency .....Each $4.60

Cat. No. JC54685B—Adapter kit for double distillation—consisting of three glass connecting tubes Each $16.50

LOW-COST WAY TO TEACH CHEMISTRY!

BUILD YOUR OWN TOPS PROJECTOR WITH THIS EDMUND PRECISION LENS KIT-SHOW LAB EXPERIMENTS IN ACTION

Now every teacher can have an overhead projector by following the easy-to-build plans for an inexpensive TOPS projector. It is described in the article by Dr. H. N. Alyea in the July issue of Journal of Chemical Education.

Within the budget of every teacher, the TOPS projector enables you to project an on-the-spot chemical experiment on a screen. Even a large group of students can see important phases and reactions as they occur—greatly magnified. Avoids individual experiments with possible student errors, accidents, and waste of materials.

As described and specified in the article, there are three lenses needed in the construction of the TOPS projector, available in a low-cost kit from Edmund. Kit includes: Two Plano-convex glass lenses, 86 mm. dia., 571 mm. focal length and one plastic Fresnel lens 10" dia. 8¹/₄" focal length.

Stock No. 70,620-ET.....$9.00 Ppd.

INEXPENSIVE OPTICAL BENCH FOR LABS, HOBBYISTS, CAMERA STORES

Now, a low-cost high precision and quality bench. Measure focal length, check optical quality, or use as a collimator. Save hours positioning elements in optical system. Base consists of Hardwood meter rod 40" long, graduated in inch and MM scales. Can be mounted on metal end supports. End support is reticle plate with front surface mirror attached. Includes: 4 low V-shaped lens holders which adjust vertically and horizontally; sliding spring clamps for holding lenses in position; complete instructions.

Stock No. 80,064-ET.....$12.95 Postpaid

EXTRA LENS HOLDER WITH SPRING CLAMP

Stock No. 60,069-ET.....$2.00 Postpaid

CHEMICAL PREDICTOR SLIDE RULE

Dial complete chemical equations in a matter of seconds. Slide Rule actually predicts and illustrates 10,000 different chemical equations as transparent dial is rotated—also makes it easy to balance the most complex equations.

Complete with easy-to-understand instructions.

Stock No. 50,333-ET.....$3.25 Postpaid

LOW-COST EDMUND ITEMS FOR . . . "AN INEXPENSIVE SPECTROGRAPH OF MODERATELY HIGH RESOLUTION."

September Feature Article Jrnl. of Chem. Educ.

3" PYREX SPHERICAL MIRROR. F. L. 30", ³/₈" thick.

Stock No. 50,082-ET.....$7.65 Postpaid

3" MIRROR MOUNT

Stock No. 50,109-ET.....$2.95 Postpaid

2" × 2" REFLECTING GRATING. 15,000 lines/in. Limited supply only—write for Bulletin #62

American Made—Terrific Buy!

STEREO MICROSCOPE

Years in development. Precision American made. Used for checking, inspecting, small assembly work. Up to 3" working distance. Clear, sharp, erect image. Wide, 3 dimensional field. 2 sets of objectives on rotating turret. 23X and 40X. 10 Days Free Trial.

Stock No. 85,056-ET.....$99.50 f.o.b. Barrington, N.J.

DIRECT MEASURING ATTACHMENT—with regular comparator reticle for on-the-spot checks of linear dimensions, diameters, radii and angles—in millimeters and inches.

Stock No. 40,486-ET.....$10.00 Postpaid

DIRECT MEASURING ATTACHMENT—with sand measuring reticle for sand and soil analysis.....or counting or measuring other particles of matter.

Stock No. 40,487-ET.....$10.00 Postpaid

GREGG Polyester

LABORATORY TOPS

With *CHEM-GUARD *(manufactured by CONOLITE)

NOW!

POLYMER RESIN CHEMISTRY HAS DEVELOPED AN ADVANCED CHEMICAL RESISTANT POLYESTER TOP

Combines many of the better qualities of . . .

- Treated Wood
- Cement-Asbestos
- Stainless Steel
- Decorator Laminates
- Stone

into a single top surfacing with these additional advantages:

- Seamless, fully formed top, cove and backsplash
- Exceptional resistance to chemicals.
- Non-porous and low absorption.
- Lightweight and easily installed.
- Non-reflective, pleasant appearance.
- Durable with minimum maintenance and no treatment needed.
- Intricate cut-outs simply executed at jobsite.
- Comfortable working surface, soft and warm to the touch.
- Ideal for use in radio chemical laboratories.
- Less glassware breakage.

CENCO'S NEW ANALYTICAL BALANCES

A. STAINLESS STEEL/JEWELED MECHANISM: solid stainless steel beam, not merely chrome plated metal. Synthetic ruby knife on synthetic sapphire plane, jeweled bearings at all critical points for long-term accuracy. **B. POSITIVE, CHAIN-DRIVEN WEIGHT CONTROL:** stainless steel chain not affected by environment or age, no cord-and-pulley drive to slip. Every model has NBS Class "S" ring weights, stainless steel, corrosion resistant, non-magnetic, precisely calibrated. **C. ALL-METAL HOUSING:** durable, rugged, minimum dust attraction. Protected with heavy, multiple-coat baked enamel finish. **D. EASY-VIEW WEIGHING CHAMBER:** non-corrosive base impervious to chemical attack from spillage. Crystal clear glass walls highly resistant to scratching, will not discolor. **E. EFFICIENT, NON-FATIGUING CONTROLS:** simple, speedy operation through natural, straight-line movement of operator's hands from side loading of sample to controls manipulation. With hands off to side, operator always has clear view of readout. **F. EASIER, MORE ACCURATE READOUT:** fixed vernier with cursor for quick, accurate readout.

EDITORIALLY SPEAKING

Two recent publications by the NSF provide data on scientific manpower of interest to those who counsel students on careers. The summary data in "Scientific Manpower—1962," NSF63-31, (Government Printing Office $0.35) supply answers to often-asked questions. For example:

Job openings reported for scientists, engineers, and technicians by the Department of Labor increased during 1962... for chemists and other natural scientists, 60% or more; for engineers, 40%; and for technicians in these fields, the demand nearly tripled.

The projections indicate an increase in requirements for more than 700,000 new engineers (including replacement of losses) by 1970 in addition to the more than 800,000 engineers employed in early 1960. This rate indicates a need for about 70,000 new engineers entering the field annually, compared with projected graduating classes in engineering averaging about 34,000.

The demand for new scientists is expected to total about 300,000 (including replacements) more than the 335,000 employed in early 1960 to meet expected needs for nearly 600,000 natural scientists by 1970. This rate indicates a need for nearly 30,000 new scientists annually, a figure which approximates the number of new science baccalaureates expected to become available for such work each year.

Among fields of science, largest proportionate growth in requirements is expected for mathematicians, which may more than double in the decade. Needs for physicists, medical scientists, and biological scientists are expected to nearly double. Largest absolute growth is expected for chemists, although the projected rate of growth is slower than the over-all average.

The prospects for meeting these demands of society for trained personnel "appear generally good." The only data at hand, of course, are numbers telling how many students are doing what at present. Trends can be seen, and factors recognized, if not evaluated.

Graduate degrees awarded in the sciences and engineering continued to rise at higher rates than did the number of bachelor-level degrees (in 1962).

Engineering doctorates increased 28% to 1200; master's degrees increased 9% to 8900; bachelor's degrees declined 3% to 34,700.

In the natural sciences (including mathematics), doctoral degrees rose 9% to over 4300; master's degrees increased 11% to 11,300; bachelor-level degrees increased 7% to about 55,700.

The totals of all college degrees awarded in 1961–62 increased over those for the previous year: doctorates rose 10%; master's 8%; bachelor's and first-professional degrees about 5%.

In engineering, there was a 17% rise in doctoral candidates (9200); 8% increase in master's degree students (35,400); the total undergraduate enrollment decreased slightly, but the number of freshmen dropped by 4% to 64,700.

Total graduate student enrollments in all natural sciences increased by about 6% to 60,700. Enrollments in physical science increased less, 3% to 26,600.

The NSF channeled $84 million during fiscal year 1962 into education and training programs in scientific and engineering fields. This represents an increase of about one third more than the amount allocated for these purposes in the previous year.

The other publication, a formidable volume of numerical data in tables and graphs, is "Two Years After the College Degree" NSF63-26 (Government Printing Office $1.75). This report deals with the post college careers of about 40,000 students who graduated in June 1958.

Over one third of the college graduates had attended graduate or professional school by 1960. The proportion of those seeking graduate degrees was highest among pre-med, philosophy, biological sciences, physics, history, and chemistry bachelor's degree holders... Of the degree candidates, close to 60% sought the master's degree, 12% the PhD, and 10% each law and medicine degrees. 87% of the master's degree candidates were women.

High concentration of credits in the major field was a characteristic of graduates who obtained their degrees in fields where the bachelor's degree can be a professional degree (e.g., engineering)... There seems to be little "waste" of those trained in fields for which there is much demand. By and large, those who majored in engineering, mathematics, the sciences, foreign languages, and health fields found employment in these areas... A feeling of being "overeducated" for the job was expressed by only 20% of the respondents, much less often by teachers than by respondents in other occupations... Also those working as scientists and research assistants in all fields least often felt "underutilized."

The data speak clearly: scientists and engineers can feel a security based on the demands of modern life. Although there are jobs at all levels, ample educational opportunities suggest the obligation to base a career on the highest possible degree of training and competence. The reward will be a life work both significant and satisfying.

Cyclobutane Chemistry

1. *Structure and strain energy*

The planar character of the skeletal carbon atoms of the cyclobutane ring has been accepted as a fact by organic chemists for many years (*1*). Modern textbooks of organic chemistry still continue to promote this idea, despite the existence of a variety of physical evidence that tends to restrict the catholicity of this concept (*2*). While the evidence for a "bent" or "folded" cyclobutane ring is neither as extensive nor as definitive as in the cyclohexane series, the data obtained during the last decade has nonetheless consistently tended to establish a warped skeleton for many of the simpler derivatives. Since the chemistry per se of these small rings has recently become both voluminous and, more important, fascinating, these conformational commentaries should properly be incorporated into the teaching of cyclobutane chemistry.

Physical Approaches to Structure

We shall review briefly some possible limiting factors in the physical studies of structure before we consider in detail the various conformations that have been proposed for particular four-membered rings. One central fact about these small alicyclic rings should be borne in mind: They are dynamic systems with finite conformational possibilities. This fact is often forgotten in considerations employing graphic formulas or molecular models (*3*). At best these are a frozen photograph of our conception of the real molecule and not, unfortunately, a moving picture film of conformational events in the molecule.

Instrumental probing for the molecular parameters on which we base our ideas of physical structure is likewise limited. One should bear carefully in mind that different techniques convey to us different kinds of raw information (*4*). Infrared and Raman measurements tell us essentially all that we need to know about the structure of a molecule even with their existing powers of resolution. Unfortunately, we can decipher this message fully only for very simple two- or three-atom molecules. By comparison, X-ray and electron diffraction techniques are only rough estimates. However, these latter techniques do allow us to locate relatively all the atoms except hydrogen even in fantastically complex structures (the hydrogen locale is presently accessible by NMR and neutron diffraction techniques).

Hence we will find on occasion that infrared or Raman techniques will suggest one conformer while X-ray or electron diffraction will suggest another. To some extent our difficulties in reaching a wholly satisfactory decision are based on the instrumental difficulties outlined above. There are also deeper underlying philosophical reasons. Pitzer cites an instance in his work with cyclopentane in which certain investigators felt unable to accept his "rippling" set of conformers for the cyclopentane molecule because of the "structural uncertainty" imposed by this concept (*5*). A remark made by Bertrand Russell some years ago is apropos in this connection: "There has been a great deal of speculation in traditional philosophy [read: chemistry] which might have been avoided if the importance of structure, and the difficulty of getting behind it, had been realized (*6*)." We are all familiar with the ancient proverb that "A thing is what it is and what it is becoming." We are further familiar with a specific application of the proverb; that is, the particle-wave duality of the electron. Such duality becomes manifest when we impose a "signal" on an electron and obtain a readable signal in return. The quality of the electronic state suggested by the signal, that is, particle or wave, depends on the particular type of perturbation. This uncertainty extends also to the molecule, which is considered to be a collection of electrons in orbitals that bear to each other and to the particular nuclei involved a most complicated set of quantal interrelationships. The echo of the principle of indeterminacy can still be heard then within the larger confines of molecular architecture. Therefore we can readily perceive that information fed back to us by instrumental interference with the processes that give "life" to the molecule is apt to consist in a multiplicity of answers rather than a yes or no answer concerning a "pet" conformation imagined by some one investigator.

The immense complexity of problems of molecular symmetry is indicated by recent developments in conformational work on the cyclohexane molecule, especially the machine computations of Hendrickson (*7*). We see here that the simple $Chair_1$-$Chair_2$ relationship is no longer a sufficient basis for explaining all of the structural aspects, properties, and reactions of cyclohexane. We appear to be confronted also in the cyclobutanes with the problem of dealing with a molecule that presents itself in various shapes, our knowledge of which is dependent both on the technique used to gather the structural parameters and probably to an even greater extent on our primitive understanding of the nature of the motions of the atoms attached to the quantized chemical bond.

Structural studies, though fraught with dangers inherent in the interpretation of instrumental data, are nevertheless of overwhelming importance for the chemistry of cyclobutane. There is no doubt that such studies will involve more precise application of the older techniques and that newer, more incisive tech-

A second article which will appear next month will discuss the reactions and mechanisms in cyclobutane chemistry.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

niques will be added. This growth and refinement of techniques is absolutely essential, since we shall have to know what the relatively-relaxed molecule, disturbed only by its surrounding twins, "looks like" before we can make a reasonably sound estimate of the particular shape of the transition state for a given reaction of this molecule. Since the chemistry of cyclopropane and cyclobutane together forms a class that might properly be dubbed "the chemistry of the abnormal or pathological C—C bond," we shall need as full an energetic and geometrical description of these molecules as possible. Such finely-detailed structural studies are mandatory to the unraveling of this truly delightful chemistry.

There are three cyclobutane conformations which have received the greatest attention as structural candidates in X-ray and electron diffraction studies. These include the D_{4h} planar, D_{2d} planar and the D_{2d} nonplanar (Fig. 1). Simple cyclobutanes tend in general to display a folded ring of symmetry D_{2d}. The dihedral angle *theta* formed between the two intersecting planes of the ring has an average observed value of about 20° for most of these compounds (*2*). However, Bastiansien has recently reported a dihedral angle of 35° for the parent hydrocarbon (*8*). The tendency toward ring-warping across the diagonal is, logically enough, thwarted by fusion of other rings with the cyclobutane skeletal carbon atoms. Biphenylene (I) for example, contains a captive cyclo-

I

butane ring in the center of the molecule and has been found by X-ray analysis to be perfectly flat. A further comment on the structure of this molecule is to be found in the chemical reactivity: the substitution reactions of biphenylene tend to be those of a ring-fused cyclobutane rather than those of a similarly-constituted cyclobutane or cyclobutadiene (*9*).

X-ray analysis also indicates a flat cyclobutane ring and centrosymmetry in the isomer of 1,2,3,4,-tetraphenylcyclobutene (II) in which the consecutive pairs

II

of phenyl substituents are alternately *cis* and *trans* around the ring (*10*). The carbon skeleton in the molecule is rectangularly disposed, reflecting possible contributions of *cis* repulsions of the phenyl groups to the lengthening of the alternate skeletal bonds. However, Meredith and Wright have suggested on the basis of measurements of the dipole moment that this isomer is neither flat nor rigid (*3*). The *cis* phenyl groups of the model are not free to rotate completely but are confined to an oscillatory motion about the C-phenyl to C-cyclobutane bond (*11*). The role of crystal forces in determining the "flatness" of this particular cyclobutane ring is not known.

With the limited data at our disposal, we can make only a gross estimate of the factors that fundamentally determine whether or not a cyclobutane with a given set of substituents will have a warped or a planar ring.

Dihedral angle, θ, is the angle between plane *A, A'*, containing carbon atoms C_1, C_2, and C_4, and plane *B,B'*, containing C_2, C_3 and C_4.

Figure 1. The *D* (dihedral) class of molecular point groups to which these three conformers belong, is characterized by a vertical principal axis, *j*, and two-fold subsidiary axes perpendicular to the principal one. The description is completed by consideration of various planes of symmetry that may be either vertical or horizontal. Thus, the D_{4h} planar form has a four-fold principal axis, *j*, (therefore D_4) and a *horizontal* plane of symmetry (therefore D_{4h}) to which the vertical planes of symmetry *k, k'; l, l'; m, m'; n, n'* are subsidiary. (Vertical planes indicated by their lines of intersection with the horizontal plane of the ring.) D_{2d} non-planar has a two-fold principal axis, *j*, (therefore D_2) and two *diagonal* (vertical) planes of symmetry (therefore D_{2d} or sometimes V_d), *o, o'; p, p'* that bisect the angles between the two subsidiary two-fold axes *q, q'; r, r'*. The latter symmetry elements also hold for the D_{2d} planar form.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

The observed entropy of the parent hydrocarbon is, for example, too large to be accounted for by a simple planar form of D_{4h} symmetry alone. Therefore the structural order of this substance is greater than one, and a mixture of conformers must be present. There are also too many bands in the infrared absorption spectra at room temperature to be accounted for on the basis of the allowed frequencies of the D_{4h} planar form. Rathjens and Freeman have on the basis of these measurements put forward the suggestion that an inversion occurs which encompasses the two possible D_{2d} nonplanar conformations as the extreme structures and the D_{4h} planar form as the mid-structure of the process (*12*) (Fig. 2). The barrier hindering this inversion is very low; as the temperature increases, the population of the planar form will increase rapidly at the expense of the bent or staggered forms.

Figure 2.

The introduction of simple substituents into the cyclobutane ring leads to a similar picture. Electron diffraction and X-ray studies on octafluorocyclobutane, methylcyclobutane, and other monocyclic cyclobutanes are suggestive also of D_{2d} nonplanar conformations. A third possible conformation, D_{2d} planar (Fig. 1), was ruled out in the electron diffraction study of octofluorocyclobutane (*13*).

Recent work concerned with physicochemical properties of the cyclobutanes also points to possible ring-folded conformers. Brewster has suggested that a diagonally-folded (D_{2d} symmetry) cyclobutane ring would best explain the similarity of the observed and calculated values of the optical rotation of the caryophyllenic acid stereoisomers (*14*). Roberts' group has, moreover, used a buckled-ring model to explain an unusual magnetic spin-spin coupling between the proton and a fluorine nucleus separated by five consecutive saturated bonds in 1,1-difluoro-2,2-dichloro-3-phenyl-3 methylcyclobutane (*15*). On the negative side, Hollis has run high and low temperature NMR studies on a group of substituted cyclobutanes and has found no perceptible change in the spectra over the range from approximately −70 to +90°C (*16*). Therefore, if these protons are subjected to an averaged environment from dynamic ring buckling, the onset of the ring buckling occurs well below −70°C. (The other, less attractive alternative is that the ring is frozen in one position and remains locked in that position throughout the given temperature range.) This latter finding is in contrast to the work of Jensen on cyclohexane (*17*). He observed a definite splitting of the ring proton signal in cyclohexane as the temperature was lowered. One source of all these difficulties in structural determination in addition to the two mentioned above is possibly to be found in the fact that the cyclobutanes are one of those strange transition structures lying between highly-strained, small cyclic structures such as cyclopropane and spiropentane, and the larger, relatively strain-free alicyclic hydrocarbons, cyclopentane, and cyclohexane. As such, cyclobutane partakes somewhat of the characteristics of each class.

Strain Energy of Small Rings

Molecular strain, like the more general term molecular stability, assumes various meanings for the chemist (*18*). The organic chemist who is faced with the problem of rationalizing the "go" or "no-go" of a small-ring reaction will look upon strain as a bond property that affects the rate or over-all result of the reaction in a special way. If the ring breaks open under exceptionally gentle circumstances, strain is thought of as the property of the bond that is responsible for facile cleavage. The bond at which cleavage occurs is thus considered weaker than normal. If the solvolysis of a small ring halide is unusually slow, strain is invoked as the property of the transition state which forestalls its production in sufficient quantities to permit a normal rate (*19*). On the other hand, the chemical physicist is generally not concerned with the consequences of strain in reactions but is concerned instead with strain as something which contributes to abnormal physical properties in the "resting" or ground state molecule (*20*). The concrete expression of strain for the latter may be an unusual value of the dipole moment (*21*), an "off-value" of a thermodynamic function that points to an unusual conformational population, or a bond force constant that is smaller than usual.

Thus a working definition of molecular strain which is satisfactory for all schools is not easily set down. We could consider strain in a limited sense to be the departure of the intraring sp^3 carbon orbitals from their normal tetrahedral mode, as found in cyclohexane. A bond maladjustment of this type is usually considered to raise the total bond energy and thus make the molecule less stable. However, strain is not, as we shall see, solely a destructive force tending to tear the molecule apart under any and all circumstances (*22*). Further, strain imparts to a ring a complex set of motions over and above the normal ones (*3*). Hence, the origin of strain in molecules and its ultimate effect on the physical and chemical properties of a given molecule are still phenomena that elude comprehensive definitions. We shall therefore merely review below certain aspects of strain energy of concern to the operating chemist and attempt to point out some of the less well-known features of the problem.

Kaarsemaker and Coops have determined calorimetrically a value of 26 kcal per mole for the strain energy of cyclobutane or 6.5 kcal per methylene group (*23*). This observed value demonstrates that the ring is indeed strained but does not permit a clearer interpretation of the nature of this strain. Several semi-empirical calculations have led to the same or somewhat higher values than the one observed (*20, 24, 25*). These latter calculations are not surprising since

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

any calculation today involving a ring as large as cyclobutane necessarily involves very broad estimates and considerable guesswork (*20*). In addition, the uncertainties in conformational assignments noted in the last section indicate that we lack a secure model on which to base calculations of the physical parameters of bond strain, such as bond force constants, the degree of departure of bond angles from their normal values, torsional effects (bond-twisting), and the effect of repulsive (or attractive) forces between the nonbonded atoms.

The qualitative picture of strain that emerges from the reactions undergone by cyclobutane and its derivatives is likewise not very enlightening, although certain general tendencies can be observed which are reagent-dependent. We have long been aware of a tendency of the ring C—C bonds to sever under a variety of chemical circumstances.[1] Further, as Roberts and his students have found, the cyclobutane framework is a flimsy, collapsible structure under conditions favoring carbonium ion formation at the ring carbons (*26*). A remarkable equilibrium is established under these circumstances in which cyclobutyl fragments coexist with cyclopropyl carbinyl, open chain, and other forms which still defy adequate description. Nonetheless, there are many circumstances under which cyclobutane (and cyclopropane) rings maintain their curious structure intact, in particular, when treated with certain oxidizing agents (*27*, *28*). Hopefully, improvements in techniques of separating mixtures and in spectral techniques such as NMR, ESR, and mass spectrometry will enable small ring chemists in the next few years to unravel much of this confusion and, finally, to achieve a firm understanding of the "rules of order" for the strained bonds in these molecules.

Although the gross structure of cyclobutane as a four-membered, "saturated" hydrocarbon ring has long been settled, the more arduous task of precisely defining the electronic and energetic composition of the C—C and C—H bonds is still in the primitive stages. However, a monumental conceptual step forward was made by Coulson and Moffitt in 1949 (*29*). The manner in which they attempted to solve the problem of the unusual C—C bond character of these small rings is instructive even today for the organic chemist. The original paper is still, in our view, required reading for those engaged in research or in teaching about small rings. The fact that the junior author, William Moffitt, was 24 years old at the time this paper was published, forms an interesting social as well as scientific commentary.

Their basic contribution was the full pursuit of the intuitive idea that the principle of maximum overlap of atomic orbitals was not inviolate. The consequent implication of a "straight-line" bond was therefore subject to reconsideration. The approach of Coulson and Moffitt enables us to see clearly and generally that a tetrahedral C—C bond can under circumstances of strain depart from tetrahedral symmetry, T_d, to the lower symmetry, C_{2v}, in small rings (Fig. 3). Even under these conditions the carbon-carbon orbitals involved can still provide a bond of considerable strength. A grasp of the implications of this concept is essential to an understanding, not only of small ring chemistry generally, but also of other related phenomena such as the Thorpe-Ingold effect (*30*).

They proceeded by selecting the "hybridization ratio"[2] of the ring carbon orbitals as the variational parameter of the molecule and minimized the energy of the molecule in terms of this ratio. Their calculations show that in the minimum energy state of a small-ring molecule, the ring carbon orbitals in, for example, cyclopropane, are at an angle of 106° to each other and not at 60°, as would be required by straight line bonds. Thus the orbitals are not in a condition of regular sp^3

Figure 3.

Figure 4.

tetrahedral overlap but are actually bent outward from the hypothetical internuclear straight line. This effect, while not so pronounced in cyclobutane, is nonetheless still present to the extent of about 20% as compared to cyclopropane. This poor overlap engenders in turn a certain amount of electron delocalization (pi character) which contributes to the stability of these ring bonds. These bent bonds are thus seen to be made up of contrasting forces: Poor overlap of the orbitals, which are nominally sp^3, tends to reduce the strength of the bond below that of a structurally comparable C—C bond in, for example, ethane or cyclohexane, while the consequent possibilities for electron delocalization contribute a stabilizing force. One should note carefully that this latent pi character of these bonds is oriented in the *same plane* as the ring carbons and not in two planes parallel to the ring as in benzene. These bent orbitals can be depicted as shown in Figure 4 and the residual pi orbital overlap by the dotted lines. This unusual type of orbital with its dual character has important chemical and physical implications. The pi character inherent in this bent ring bond has been known empirically for many years. The facile ring-opening of cyclopropane with bromine and the more reluctant ring-opening that results on the catalytic hydrogenation of cyclopropane and cyclobutane with Raney nickel catalyst are well-known

[1] *Cf.* part 2 of this paper to be published in THIS JOURNAL.

[2] This term dictates how much "*p*-orbital character" shall be mixed with the *s*-orbital to provide a proper bonding orbital for a given symmetry.

examples of this ethylene-like behavior (*25*). Subsequent developments have disclosed that both of these small rings, when appropriately substituted, can be cleaved readily with a wide variety of reagents. This array of chemical cleavages is thus indicative of a special property of these small ring bonds. This can be generally attributed to an availability of electrons of the ring bonds considerably above that of a normal sigma C—C bond. For the moment, super electron availability in these bonds can be ascribed to "pi-like character" as the handiest common coin of bond language.

Figure 5. Vinylcyclobutane. Dotted area indicates main pi orbital conjugated with the ring. Slanted line area indicates sigma orbital overlap of ring carbons.

Thus one would expect conjugative powers for these small ring bonds similar to but considerably weaker than ethylene This has been demonstrated by Cromwell on the basis of the spectral properties of conjugated systems which incorporate a cyclopropane ring as a substitute for one of the ethylenic units (*31*). According to Cromwell, conjugation of a clear-cut pi-electron system such as a vinyl or carbonyl group can occur with these small rings only when the bent orbitals of the small rings are in the same plane with the pi orbitals of the attached group (Fig. 5). While somewhat controversial, Cromwell's views are supported by his data which is part of a growing body of evidence indicating that cyclopropane, at least, does possess conjugative powers similar to ethylene. The evidence for the cyclobutane ring is not as abundant or as definite but even here some conjugative ability appears possible (*32*). This ethylene-like character is curiously absent in reactions with oxidizing agents. Neither cyclopropane nor cyclobutane are known to be attacked by ozone (*28*). However, cyclohexane, which is certainly more strain-free and more "aliphatic" in character than these small rings, is largely converted on prolonged ozonization into a mixture of products of which cyclohexanone and adipic acid have been identified (*33*). All of this work should probably be repeated under the control of a single investigator. In view of the known sensitivity of many cyclobutane derivatives to light, ozonization of this small ring in the presence of light might prove interesting.

This stability to oxidizing agents may conceivably be rooted in the unusual pi characteristics of these bent ring bonds as indicated by the work of Coulson and Moffitt. While these bonds are characterized as bent *away* from the hypothetical straight line joining the ring carbon nuclei, they are at the same time bent below the tetrahedral angle of 109°.[3] They should thus be designated as a kind of super sp^3 or sp^{3+} hybrid orbital. There is unfortunately no simple way of relating this hypothetical concept to the observed stability of small rings to oxidants. This is, however, not the usual stability of a closed pi system since such systems are fragmented by ozone. Here is an area in which, as Pauling has suggested, the pi-sigma concept of bonding meets a practical test of survival and from which such a concept may not emerge intact (*34*).

However, with these reservations, the very valuable orbital details of these small rings given by Coulson and Moffitt enable us to "see" the bond-weakening affects of strain in these molecules at the level of the electron pathway as well as to understand the possibility of the existence of residual ghost pi orbitals that encircle a molecule and thus bind it together in spite of the strain. Further, Coulson observed that there is possibly an area of increased electron density in the center of the cyclopropane molecule. As Coulson himself has said in another connection, further theoretical progress in the area of orbital strain should properly await the amassing of definitive laboratory work (*35*). The theoretician may thus know more clearly that which he must describe in precise terms and enlarge upon predictively.

A square planar model with local symmetry C_{2v} at each carbon atom was used by Coulson and Moffitt in their work on the disposition of ring orbitals in cyclobutane. As we have seen, evidence for the presence of crumpled conformations in cyclobutane has continued to accumulate since that paper was written. While the departure from planarity is considered to be small, relative to a molecule such as cyclohexane, renewed attempts at a quantum mechanical description of this molecule should take these conformations into account. Since strain energy and conformations are intimately related, a qualitative review of certain conformational aspects of this molecule can be of assistance in our attempts to understand the sources and effects of strain.

There are many anomalies in small rings that are as yet begging for a clear explanation. One such problem arises from the fact that the ring bond of cyclopropane is slightly shorter (1.524 Å) than a normal C—C single bond (1.540 Å) whereas that of cyclobutane is somewhat longer (1.548 Å). A strained bond, because of its increased tendency to undergo cleavage with the appropriate reagents, would be considered as weaker and, therefore, longer. Coulson and Moffitt explained the short bond in cyclopropane as follows: Since the bond is bent, the line of maximum electron density which corresponds to the actual bond will follow an arc which is of greater length than the hypothetical straight line joining the carbon nuclei. The actual bond is therefore said to be longer than one is led to believe by, for example, electron diffraction studies, which locate only the relative position of the nuclei. However, the long bond of cyclobutane is clearly not explainable solely on the basis given for cyclopropane.

In our efforts to unravel such puzzling molecular features, we are forced to consider and weigh simultaneously the contributions of a multiplet of conformations. As we have noted before, one can no longer elaborate structural theory for these small rings on the basis of a rigid, inflexible nuclear framework. Even the smallest of the cyclic molecules, cyclopropane, probably undergoes a continual change of conformations similar to cyclopentance (*36*). This alleged change would be manifested by a torsional hydrogen staggering in

[3] Coulson and Goodwin (*J. Chem. Soc.*, 1962, 2851), have recently carried through a rough M.O. calculation of these C—C bond angles: cyclopropane, 108° 48′, and cyclobutane, 111° 28′.

consequence of single carbon oscillation (Fig. 6).

The conformational alterations in cyclobutane must become even more involved because of the additional methylene group. Dunitz and Schomaker have suggested that a prime cause of the long bond in cyclobutane might well be the cross-ring repulsion of the

Figure 6.

1,3 carbon atoms (*37*) (Fig. 7). This would not be possible in cyclopropane, since each carbon is bound to only two neighbors. Hence none of the carbons in this ring "looks at" a middleman carbon. In support of this proposed repulsion in cyclobutane, they cite the fact that the 1,3 pair of carbon atoms is 0.3 Å closer (2.2 Å) together than the corresponding 1,3 carbon atoms in cyclohexane (2.5 Å). Consequently, the repulsive forces between these diagonal pairs of carbon atoms in cyclobutane should be considerable.

Figure 7.

This proposal is an attractive one conceptually and points to a possible explanation of a good part of the strain energy in cyclobutane. Herein may lie also an explanation of the bending of the ring. Let us assume that the molecule would either have to expand in one plane (breathing) or twist out of the plane with a coupled torsional motion in order to compensate for this repulsion. The latter seems more plausible, since rotation about a bond can normally be accomplished with a smaller expenditure of energy than bond-stretching. The twisting in cyclobutane would involve most logically a diagonal pair of carbon atoms or, rather, both pairs simultaneously.

This would appear to be a more economical route for a four-membered ring than the single carbon twist characteristic of cyclopentane. Using this assumption one can account for the many observations of the form of D_{2d} symmetry in electron diffraction and X-ray work. The only alternative is to insist that such cross-ring repulsion would tend to maintain the carbon nuclei in the same plane. The latter avoids certain conceptual weaknesses in the former argument but fails to explain the structural observations.

Since the molecule does show a tendency to escape the planar conformation, we should examine all of the possible means of increasing the stability of the molecule in the bent form. For this purpose we should, of course, like to relate cyclobutane to a simpler model. The barrier to free rotation of the two methyl groups comprising ethane is probably in the last analysis a very simple example of strain energy. We could imagine cyclobutane as a substituted ethane in which two vicinal protons are replaced by a dimethylene bridge. However, after 30 years of prodigious effort, even this simple manifestation of strain is still wrapped in friendly controversy (*38*).

Another possible approach to cyclobutane, still largely empirical, is the recently proposed "principle of minimum bending of orbitals" under development by Eyring and his group (*39*). This principle is based on one of the most difficult areas of quantum mechanics,

Figure 8.

that of the kinetic energy of the bonding electron. However, this rule appears to us to be capable of considerable conceptual development and holds out the promise of lending assistance in problems such as this one. Re-examination of the problem of dihedral bending in cyclobutanes in the light of this principle yields a partial answer to the riddle of "Why the molecule bends at all." Conceivably, the planar molecule could be pulled into the D_{2d} conformation by the opportunity for a *trans* electron delocalization involving the H_1—C_1—C_2—H_2 nuclei (Fig. 8). The right side of this equilibrium would be terminated by a new set of growing forces that would tend in turn to push this conformational equilibrium toward the left. These new forces are the repulsive ones that would be increasing as carbon atoms 1 and 3 approach each other and the angles between the ring bonds decreased. This scheme would entail a loss of co-planarity as the molecule departs from the planar form. Hence, any stabilization resulting from electron delocalization in the plane of the ring would be sacrificed. However, as noted above, this effect is presumably not very large in cyclobutane. Some gain in stability would occur as a result of an eightfold (or sixteen for the two D_{2d} forms) *trans* staggering of nonbonded H atoms.[4] We are thus able to explain the following observations:

1. There can be two coexistent conformations, D_{4h} and D_{2d}, in dynamic equilibrium.

2. The C—H bonds would be somewhat stronger than those in ethane because of increased delocalization of the C—C bonding electrons toward the C—H bonds in cyclobutane. This has been verified experimentally by the observation of an increased H—C—H angle to 112° (increased sp^2 character). Some additional stabilization of the C—H bond may also be realized through relaxation of the nonbonded H—H repulsion (*40*).

Another unique manifestation of strain energy in

[4] There are actually two sets of spacially nonequivalent ring hydrogens which come into being as the ring bends (see Fig. 1). The axial set achieves coplanarity with the associated carbon nuclei at a dihedral angle of about 60°. The equatorial set, of course, does not.

certain cyclobutanes is the case with which they decompose to ethylenes. In a manner of speaking, these four-membered rings appear to possess a built-in memory of their ethylenic origin. Thus cyclobutanes in many instances can be neatly broken into their component ethylenes by thermal urging. Srinivasan and Kellner demonstrated in an elegant study of the pyrolysis of cyclobutane 1,1,2,2-d_4 at low pressures that a unimolecular decomposition occurs as illustrated in Figure 9 (*41*). No CH_2CD_2 was observed in thermal splitting of mixtures of cyclobutane and cyclobutane d_8, so we have reasonable assurance that the pyrolysis of cyclobutane is of the simplest possible type: a unimolecular C_2—C_2 split uncomplicated by hydrogen

Figure 9.

exchange. Neat fragmentation can also occur in the liquid phase. For example, Gundermann in his studies on the cyclodimerization of β-mercaptoalkylacrylonitriles to the respective cyclobutanes has also observed quantitative splitting of the dimer into the monomer under the proper conditions (*42*). Reverse cyclodimerization has, of course, long been known to occur when cyclobutane photodimers are exposed to "short" ultraviolet light (*43*).

The ready reversibility of some of these reactions present a possible opportunity for the study of strain energy in four-membered rings by the use of appropriate kinetic and thermodynamic techniques.

Two Unsolved Problems

The dimerization of ethylene to cyclobutane has not been observed. The prospects of such an accomplishment are discouraging when viewed historically. Ethylene has indeed been exposed to an enormous variety of experimental conditions which were calculated to produce higher molecular weight hydrocarbons. In no instance has cyclobutane appeared in the products. However, much of this work was done before the advent of gas chromatography and hence trace amounts would probably have gone undetected. Infrared and Raman spectral measurements which have been done on the products of such work are open to question. Attempts to identify peaks definitely characteristic of a unique ring motion (skeletal vibrations) for cyclobutane in these spectral regions have not been successful (*44*). One thermochemical calculation showed a small (minus 25 kcal) but favorable enthalpy change for this cyclodimerization (*45*).

Pease analyzed the problem indirectly some years ago in a paper concerned with ethylene polymerization (*46*). He pointed out that a "quasi-molecule," C_4H_8, consisting of two activated ethylene molecules would have a vanishingly small lifetime. During this short time the sum of the activation energies of the two ethylene molecules would have to be jettisoned in a quantized fashion. Such energy dumping is therefore subject to the dictates of the uncertainty principle and the principle of the conservation of momentum. The transition state of this cyclodimerization, if achieved at all, must resemble two loosely-bonded molecules of monomer. We assume that under these circumstances very few degrees of internal freedom would be available. Consequently, there would be little probability of "concealing" any sizeable amount of additional molecular energy within the incipient bonds for any length of time. Nor would the similar electronegativities of carbon and hydrogen contribute to stability in this instance. All these factors argue against the existence of a stable (long-lived) excited state in sufficient population numbers to permit the reaction to move down the product side of the energy hump.

Several related reactions which have been discovered recently offer some promise that the cyclodimerization of ethylene will eventually be achieved, although in a manner more elaborate than the purely thermal. The reactions listed below are rough analogues of this cyclodimerization in one way or another. However, in each instance some special assistance factor is present:

(1) The photocyclization of myrcene to β-pinene (*47*).

Table 1

Ring size	Number of carbon atoms in ring 4	5	6	7
Borohydride reduction of monoketone[a] ($k_2 \times 10^4$ 1 mole^{-1} sec^{-1})	264.0	7.01	161.1	1.02
Solvolysis of tosylates[a] at 70° ($k_1 \times 10^5$ sec^{-1})	26.7	32.2	2.37	60.0
Solvolysis of 1-chloro-1-methyl cycloalkanes[a] at 25° ($k_1 \times 10^2$ hr^{-1})	0.224	132.0	1.06	115.0
Solvolysis of allylic bromides[b] (relative rates at 0°C)	1.0	3500.0	2.7	...
Dissociation constants of ketone cyanhydrins at 20°C in 95% ethanol,[d] ($k \times 10^2$)	0.87	1.91	0.176	9.53
Oxidation of cycloalkanes by chromic acid[e] rates per methylene group ($(k_{ox/n})\ 10^2\ k_{ox/n}$)	0.0640	1.26	0.212	2.98
Enol content of monoketone (%)[f]	0.55	0.09	1.18	0.56
Ratio of dissociation constants of 1,3-*trans*-dicarboxylic acids (K_a^1/K_a^2)[g]	29.5	11.2	26.0	...

$$2\,H_2C = CH_2 \rightarrow CH_3 - CH = CH - CH_3 + CH_2 = CH - CH_2CH_3$$

Some years ago Roberts and Chambers made a thorough study of the properties of alicyclic ring compounds (*50*). In general, they found that a number of properties would indeed change in a more or less regular fashion as one ascends the series. However, in the course of preparing this review, we observed a curious alternation of properties which was particularly marked for the subset, cyclobutane, cyclopentane, cyclohexane, and cycloheptane. These are tabulated below for the C_4-C_7 hydrocarbon derivatives.

We cannot possibly judge whether the similarity of properties between cyclobutane and cyclohexane derivatives is indeed indicative of the participation of a "bent" conformer of cyclobutane. To do so at this stage would be tantamount to invoking the "Rule of Selective Inattention to Data."[5] However, one group of investigators is attempting to locate the "axial" and "equatorial" groups in cyclobutanes by means of microwave spectroscopy (*51*). This investigation and the others cited previously proves, we believe, our general contention: namely, that cyclobutanes "in the real and in the round" are far less symmetrical than the graphitic flat square would imply. If this be so, then chemical evidence for this will begin to occur "at the bench." We can only conclude, with A. M. Whitehead, that "Panic of error is the death of progress (*52*)."

---

[5] We wish to thank Dr. Irving Tabachnik of the Schering Corporation for pointing out to us this succinct formulation of this curious rule of human behavior.

Crystals, Minerals, and Chemistry

The intimate relationship between mineralogy and chemistry was established in the late eighteenth and early nineteenth centuries, when Haüy (1743–1822) and Mitscherlich (1794–1863) examined the relationship between crystal form and chemical constitution. Haüy was convinced that identity of crystal form meant identity of chemical constitution, and conversely, that difference of crystal form meant difference in chemical constitution (*1*). The first of Haüy's convictions was controverted by Mitscherlich's work on the isomorphic character of the potassium acid phosphates and arsenates (*2*); of potassium sulfate, selenate and manganate (*3*), and of potassium permanganate and perchlorate (*4*). The conclusion from this work was formulated by Mitscherlich in his principle of isomorphism[1] which played a notable role in the determination of chemical formulas, valence, and atomic weights. The second of Haüy's convictions was shown to be erroneous when Mitscherlich discovered the dimorphism of sulfur (*5*); and it was finally disproved for compounds, too, when chemists accepted the analytical data from samples of aragonite which contained no strontium. The Haüy school had claimed (*6*) that the strontium commonly found in aragonite structures forced the calcium carbonate to adopt the strontianite structure rather than the calcite structure; the existence of a strontium-free aragonite proved this hypothesis incorrect.[2]

Although the nineteenth century saw many descriptions of mineral substances, many measurements of angles, and elaborate classifications of minerals, the definitive study of crystals had to await the development of X-ray diffraction methods for crystal structure analysis.

Of fundamental importance in connection with this new approach to crystal chemistry were the early structure determinations of W. H. and W. L. Bragg, the empirical ionic radii of V. M. Goldschmidt, and Pauling's "rules" for the determination of crystal structures. Today, additional techniques are available, such as neutron diffraction, nuclear magnetic resonance, differential thermal analysis, and infrared absorption spectroscopy. All of these methods have contributed to a detailed knowledge of crystallography and mineralogy.

Nevertheless, simple chemical analysis gives much information about minerals, and shows that the textbook concepts of stoichiometry must be abandoned when dealing with oxygenated systems in the solid state.

Stoichiometry and Isomorphism

Most chemists are familiar with the two series of carbonates of divalent cations listed in Table 1. Not so well understood, however, is the fact that crystals of these substances often are not "pure" carbonates of a single cation, but contain more than one cation, as in the strontium-containing aragonite which confused Haüy and his adherents. The strontium is not there as a separate strontium carbonate phase. Only one phase is present, with the strontium ions substituted at random for calcium ions in the aragonite structure.

Table 1. Two Isomorphic Series of Carbonate Minerals

Rhombohedral ($R\bar{3}c$)	Formula	Cation Radius (A)	Orthorhombic ($Pmcn$)
Calcite	$CaCO_3$	0.99	Aragonite
Rhodochrosite	$MnCO_3$	0.80	...
Siderite	$FeCO_3$	0.74	...
Smithsonite	$ZnCO_3$	0.74	...
Magnesite	$MgCO_3$	0.66	...
...	$SrCO_3$	1.12	Strontianite
...	$PbCO_3$	1.20	Cerussite
...	$BaCO_3$	1.34	Witherite

Some persons call such a substance an isomorphic mixture, but it is not a mixture in the sense that more than one phase is present. Others would speak of it as a solid solution, but the term solution is so familiarly used in connection with liquids as to imply a lack of spatial organization. To overcome these difficulties, the more general term *isomorphic variant* has been proposed.

Isomorphic variants for both of the forms of Table 1 are common. In the calcite group there are various compositions of iron-bearing smithsonite or zinc-bearing siderite, and crystals containing various amounts of manganese in addition to iron and zinc. In addition to the strontium-calcium variants in the aragonite group, there exist barium-calcium and lead-calcium carbonates. For all these cases it must be emphasized that only a single phase is present. The factor which determines the crystal form of the carbonates is the cation radius, with 0.99 Å representing the value common to both structures. When the cations are in about equal amounts, they tend to assume

[1] Mitscherlich, E. (ref. (*2*), p. 79): *"Ett lika antal atomer, då de äro på lika sätt förenade, frambringa like krystall former, och krystall formen beror ej af atomernas natur, utan af deras antal och föreningssätt."* (Equal numbers of atoms, combined in the same way, produce similar crystal forms, and the crystal form does not depend upon the nature of the atoms but on their number and mode of combination.)

[2] Mitscherlich had already suggested the conjugate of isomorphism in his 1821 paper before the Swedish Academy (ref. (*2*)): *"En och samma kropp, som ar sammansatt af samma ämnen efter samma proportioner, kan antaga tvenne olika former."* (The same body, composed of the same substances, in the same proportions, can take on two unlike forms.)

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

specific positions in the crystal lattice, rather than appearing in a random arrangement. The appearance of two kinds of atoms in positions formerly occupied by calcium ions causes the crystal to lose some of its symmetry characteristics, and instead of the internal structure of calcite, the structure of dolomite, $CaMg(CO_3)_2$, and ankerite, $CaFe(CO_3)_2$, is observed. These minerals still belong to the rhombohedral class although their internal (space group) symmetry is lower. To accommodate the larger barium ion, however, a different external form is also required, so that $CaBa(CO_3)_2$ is monoclinic.

Still more complex variants occur among the silicates. While orthoclase is clearly a monoclinic crystal closely approaching the formula $KAlSi_3O_8$, the triclinic plagioclase feldspars which make up the common igneous rocks have compositions intermediate between $NaAlSi_3O_8$ and $CaAl_2Si_2O_8$, so that a particular crystal might have an analysis represented by the formula $Na_{0.68}Ca_{0.32}Al_{1.32}Si_{2.68}O_8$.

Isomorphic Substitutions

The substitution of one ion for another without significant disturbance of the structural arrangement is called *isomorphic substitution* or diadochy. As has already been observed for the equi-atom calcium-barium carbonate, the tendency for this substitution to occur without change in structure depends upon the sizes of the ions or ionic groups involved. Thus sodium, which has about the same ionic radius as calcium, can replace the latter fairly readily and to a significant extent. The larger potassium ion, on the other hand, is either absent or is present only in very small amounts in structures for which the principal cation is calcium.

Although it is frequently true that the substituting ion has the same charge as the substituted one, as in the isomorphic carbonate variants discussed above, the sodium-for-calcium substitution in the feldspars indicates that this is not a rigorous requirement. Here the substitution of monovalent sodium for the divalent calcium of the unsubstituted $CaAl_2Si_2O_8$ has been accompanied by an increase in the silicon content and a decrease in the aluminum content. While the external form remains essentially unchanged by this substitution and charge compensation, the X-ray patterns show that changes have occurred in the positions of ions in the crystal. The Al ion is larger than Si and the Ca ion is larger than Na, so changes in the unit-cell dimensions do occur as an accompaniment of compositional changes. It must be emphasized, however, that the crystal lattice should not be looked upon as defective, in the sense of having vacant positions; merely minor rearrangements have occurred through substitution of sodium and silicon for calcium and aluminum.

Another common occurrence is the addition of hydrogen to a structure, forming (OH) groupings of lower charge than that of the oxygens. The tiny proton cannot substitute for metallic cations in the structural positions previously occupied by them. If hydrogen is to enter the crystal structure, it must do so as hydroxyl, ammonium, or hydronium ions, whose radii are comparable to those of the ions they replace. It can, of course, also occur in the status of water molecules.

Coupled Substitution

Another way in which substitution of cations of dissimilar charge can occur is for the cation substitution to be coupled with an anion substitution. A striking example of this is offered by the isostructural minerals berlinite, an aluminum phosphate ($AlPO_4$), and the low-temperature form of quartz ($SiSiO_4$). Both of these substances show the same symmetry characteristics, and both form right-and left-handed crystals, although one can be considered to have a $+3$, -3 oxidation state and the other a $+4$, -4 oxidation state. For classification purposes, it is often more convenient to fix one's attention on the positive oxidation states alone, and look upon this as a "coupled diadochy" in which AlP substitutes for SiSi. Thus this case can be considered to be similar to the substitution of CaAl for NaSi in plagioclase feldspar, or of CeNa for 2Ca in apatite ($Ca_{10}F_2(PO_4)_6$) to give britholite $Ca_{10-2n}(CeNa)_nF_2(PO_4)_6$).

Substitution of Anions

The disparity in sizes of silicon and phosphorus in one instance, and of silicon and aluminum in the other, preclude the formation of isomorphic variants between the two end members, berlinite and quartz. The hydrogarnets, on the other hand, are the variants connecting the two isostructural extremes represented by the mineral grossular, $3CaO \cdot Al_2O_3 \cdot 3SiO_2$, and tricalcium aluminate hexahydrate, $3CaO \cdot Al_2O_3 \cdot 6H_2O$. The X-ray data demonstrate that both of these compounds and the hydrogarnets $3XO \cdot Y_2O_3 \cdot (3\text{-}n)SiO_2 \cdot 2nH_2O$ have 96 oxygen atoms in the unit cell, and that these oxygens occupy the same structurally equivalent positions in all three compounds (*7*). Since the silicate ions in grossular have the tetrahedral configuration characteristic of SiO_4, it must be supposed that when the silicon atoms are replaced by hydrogen atoms in the "hydrated" compounds at the rate of 4 protons per Si^{4+} (to maintain electrical neutrality), the tetrahedral configuration of the oxygens is maintained. Because of their low scattering power for X-rays, the protons cannot be located by X-ray techniques, but it can be assumed that they are closely associated with the oxygen atoms, at the same time remaining as far removed as possible from each other and from the calcium and aluminum ions. The most symmetrical positions for the protons would be the centers of each of the four triangular faces of a tetrahedron which has an oxygen at each apex. In any case the simplest formulas for grossular and the hydrogarnet variants should be written

$$Ca_3Al_2(SiO_4)_3,\ A_3B_2(SiO_4)_{3-n}(H_4O_4)_n,\ A_3B_2(H_4O_4)_3.$$

Synthetic compounds in which A is Ca or Sr and B is Al or Fe have been investigated. In these formulas the H_4O_4 groups represent "tetrahedral hydroxyls."

The group H_4O_4 can also substitute for phosphate and sulfate in the complex minerals listed in Table 2. In these cases the substitution of the anion must be coupled with cation substitution, because of the difference in the oxidation states of H_4O_4 and the other anions.

The extent to which the simple anion substitutions observed by Mitscherlich in his studies of the isomorphism of phosphates and arsenates can be carried, in complex minerals, was first shown in 1937 in the study

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

of the mineral ellestadite (*8*). All the physical properties of ellestadite, a calcium sulfate-silicate $Ca_{10}(F,OH)_2(SO_4)_3(SiO_4)_3$, are similar to those of apatite, with which it is isostructural. Table 3 shows some of the wide range of apatite minerals, all of which may be considered as derivatives of, and all of which are essentially isostructural with, apatite. A predominant feature of all of these minerals is that they contain 24 oxygen atoms per unit cell (except where OH or O substitutes for F) and that the other atoms fit themselves to the pattern set by the oxygens.

Table 2. Mineral Examples of Isomorphic Substitution of Anions

H_4O_4 *substituted for*		
SiO_4	PO_4	SO_4
Hydrogarnets	Griphite	Ettringite
Coffinite	Viséite[a]	
Montmorillonite	Apatite	
Antigorite	Crandallite	
$ZrSiO_{4-x}(OH)_{4x}$		

PO_4 *substituted for* SiO_4

Griphite, a phosphate garnet
Viséite, a phosphate zeolite (analcime)[a]
Berlinite, $AlPO_4$ with quartz structure

SiO_4 *and* SO_4 *for* PO_4

Ellestadite, a sulfate-silicate apatite $Ca_{10}(F,OH)_2(SO_4)_3(SiO_4)_3$

[a] Viséite has a framework structure of the type $A[XY_2O_6]\cdot H_2O$ (X is Al for analcime and Y is Si) in which case the tetrahedral oxygens are linked to form $(AlO_2)^-$, $(SiO_2)^0$, $(PO_2)^+$ and $(H_3O_2)^-$, so that the number of protons associated with the 4 shared oxygens is 3 rather than 4. Except montmorillonite and antigorite, other examples are orthosilicates or orthophosphates.

Table 3. Isomorphic Variants and End Members of the Apatite Group, $Ca_{10}F_2(PO_4)_6$

Mineral	Substitutions for Ca	Substitutions for F	Substitutions for PO_4
Ellestadite	...	...	SiO_4, SO_4[a]
Svabite	...	...	AsO_4[a]
Mimesite	Pb[a]	Cl[a]	AsO_4[a]
Vanadinite	Pb[a]	Cl[a]	VO_4[a]
Pyromorphite	Pb[a]	Cl[a]	...
Fermorite	Sr	...	AsO_4
Belovite	Sr, R.E.	...	...
Dehrnite	Na	OH	CO_3
Lewistonite	K	OH	CO_3, AlO_4(?)
Manganvoelkerite	Mn	O	...
Abukumalite	Y, Th	O	SiO_4, AlO_4
Britholite	Ce, Na	...	SiO_4
Francolite[b]	...	...	CO_3
Dahllite[b]	...	OH	CO_3
Synthetic	Cd[a]	...	...
Synthetic	...	Cl	CrO_4
Synthetic	Na	...	SO_4
Synthetic	Al	...	AlO_4

[a] The substitution is essentially complete (end members).
[b] A distinction between dahllite, containing <1% F, and francolite, containing >1% F, is important with respect to the composition of teeth and bones of living animals as contrasted with fossil teeth and bones.

Oxygen Atoms per Unit Cell

The relation of the number and symmetrical arrangement of oxygen atoms in the unit cell to the existence of isostructuralism is an important crystallochemical criterion for recognition of isomorphic variants. An experimental value of the number of oxygen atoms can be readily calculated from the measured density, the chemical analysis, and the X-ray data on the volume of the unit cell. The equation used is

$$n_0 = \frac{D\,V\,N_0(C_1P_1 + C_2P_2 + C_3P_3 + \ldots)}{M\,\Sigma_c}$$

where

n_0 = number of oxygens per unit cell
D = experimental density
V = volume of the unit cell in cubic centimeters
N_0 = Avogadro's number
M = the atomic weight of oxygen
Σ_c = summation of the weight percentages of oxides
$C_1, C_2 \ldots$ weight percentages of oxides
$P_1, P_2 \ldots$ atomic weight ratios of oxygen to formula weights of oxides (e.g., for SiO_2 this is 32/60.06 = 0.5328.)

There is, however, little probability that this calculation will yield an integer, but the correct integral number of oxygen atoms usually can be ascertained from adequate knowledge of the crystallographic symmetry.

As applied to schallerite (*9*) the calculated number of oxygen atoms is 105.2. This experimental value can now be corrected to the true value by considering the hexagonal symmetry of the crystal.

The crystallographic data indicate that the number sought must be divisible by 2 and probably divisible by 8. Large prime numbers and small multiples of fairly large prime numbers can usually be excluded as highly improbable. Thus, for this particular case, 101, 103, 105, 107, and 109 can be eliminated. Between 100 and 110, the remaining choices are 102, 104, 106, and 108. Inasmuch as 106 represents twice 53, it can be eliminated, but 104 can be split in various ways which are compatible with hexagonal symmetry:

$$104/2 = 52 = 48 + 4 = 6\cdot 8 + 4$$

$$104/4 = 26 = 24 + 2 = 3\cdot 8 + 2$$

It is deduced from such considerations that the number of oxygens in the unit cell of schallerite must be 104, which is within about 1% of the calculated value.

Similarly, for ettringite (*10*), the number of oxygens was calculated from three different sets of analytical data as: 368.3, 395.1, and 401.7. Nevertheless, from striking similarities to the known crystal structure of thaumasite (*11*), it was readily deduced that the only reasonable number is 384, because this number is divisible by 8 but not by 5. The number 5, particularly as a factor, is highly improbable inasmuch as it cannot occur as a generator of symmetry operations.

Ettringite is particularly interesting because comparison of its structure with that of thaumasite indicates that carbonate can substitute for sulfate and silicate. Mutual replacement of sulfate, silicate, and phosphate, as shown in the lower half of Table 2, is not surprising, inasmuch as these groups are all tetrahedral in shape, and their sizes, though different, are sufficiently similar to permit compensating effects through substitutions of cations. Tetrahedral hydroxyls would be expected to be somewhat larger than other tetrahedral groups, and indeed, their occurrence is accompanied by larger unit-cell dimensions than those obtained for comparable anhydrous silicates, phosphates, and sulfates.

The carbonate group, on the other hand, is not tetrahedral, and there is no evidence that the coordination number of carbon in thaumasite differs from its normal value of 3; nevertheless, the X-ray data show that the oxygen atom configuration retains the tetrahedral structure characteristic of sulfate and phosphate. This is shown (Fig. 1) by the comparison of the reflection intensities as a function of interplanar spacings

for ettringite and for a synthetic calcium carbo-aluminate." The latter can be considered the carbonate end member of the family that has ettringite as the

Figure 1. Graphic representations of the intensities and interplanar spacings for the X-ray powder diffraction maxima of calcium carbo-aluminate, calcium silico-aluminate and ettringite, all of which appear to be structurally related to thaumasite. (All data are from publications of the National Bureau of Standards.)

opposite, sulfate, end member, and thaumasite as an intermediate isomorphic variant containing no aluminum.

[3] Haüy, R. J., *Traité de Minéralogie*, Paris, 1822, Vol. 1, p. 503. In the second edition of his treatise, Haüy questions Werner's supposition that certain apatites are not merely mixtures of two phases in the following language: "*A l'égard de la chaux phosphatée grossière de l'Estramadure, il n'y a non plus aucun motif pour la placer dans une espèce à part, ainsi que l'a fait Werner, qui lui a donné le nom 'phosphorit'.*" (With regard to the crude calcium phosphates from Estremadura (Spain), there is no reason at all for placing them in a separate species, as was done by Werner, who gave them the name *phosphorite*.) The term phosphorite is currently used as the name for a rock composed essentially of calcium phosphate minerals (McConnell, D., *J. Geol.*, 58, 16 (1950)).

The carbon atoms in these compounds must be located not at the central site, as for the sulfur or phosphorus atoms, but at the center of a triangular tetrahedral face. Hence, one of the oxygen atoms previously comprising the tetrahedron is away from the sphere of influence of the carbon atom and must shift its positoin slightly to seek other friendly neighbors. This type of substitution appears to be particularly apt in hexagonal structures, and occurs in several of the apatite-like minerals, such as francolite (*12*) and dahllite (*13*) (Table 3), and in rhabdophane (*14*). In fact, the possibility of the existence of carbonate-apatites was suggested more than 140 years ago.[3]

"The Naming and Indexing of Chemical Compounds from Chemical Abstracts"

This publication is the introduction to the Volume 56 (January–June, 1962) Subject Index of *Chemical Abstracts*. It represents a comprehensive, 98-page discussion of chemical nomenclature as applied to inorganic as well as organic compounds for systematic indexing, with a classified bibliography, an index, and the appendixes (lists): (I) Miscellaneous chemical prefixes, (II) Inorganic groups and radicals, (III) Anions, (IV) Organic groups and radicals, and (V) Organic suffixes. It should prove to be of great importance and usefulness for every chemist.

Copies may be ordered at $5 per copy by writing to The Chemical Abstracts Service, The Ohio State University, Columbus 10, Ohio. For special rates on multiple copies for educational courses, write to the above address.

Deviations from Raoult's Law

It is often assumed, and has sometimes been stated explicitly in text books,[1] that there are only two thermodynamically possible ways in which a binary mixture can deviate from Raoult's law, namely either that the deviations shall be everywhere positive for both components, or that the deviations shall be everywhere negative for both components. Certainly no such restriction is imposed by thermodynamics and there are in fact several contrary examples.

The only thermodynamic restriction on the partial pressures (strictly fugacities) p_1 and p_2 of the components of a binary mixture is that they must satisfy the Duhem-Margules relation

$$(1 - x)(d \ln f_1/dx) + x(d \ln f_2/dx) = 0 \quad (T, P \text{ constant}) \qquad (1)$$

Here x is the mole fraction of component 2, and f_1 and f_2 are the activity coefficients defined by

$$f_1 = p_1/(1 - x)p_1^\circ, \qquad f_2 = p_2/xp_2^\circ \qquad (2)$$

where p_1° and p_2° are the vapor pressures of the pure substances.

Does equation (1) imply any general restrictions on the signs of $\ln f_1$ and $\ln f_2$, that is on the signs of the deviations from Raoult's law? One such restriction is readily derived but it is a much less severe restriction than that challenged in the first paragraph. Integration by parts of equation (1) between the limits 0 and 1 leads to the equation

$$\int_0^1 \ln(f_1/f_2)\, dx = 0 \qquad (3)$$

which has often been used (*1, 2, 3*) to test liquid-vapor equilibrium data for thermodynamic consistency. Since it follows from (1), equation (3) is a *necessary* condition for thermodynamic consistency, but since it is less restrictive than (1) it is not a *sufficient* condition. For example, the equations in $f_1 = Ax$ and $\ln f_2 = A(1 - x)$ satisfy (3) but fail to satisfy the Duhem-Margules relation (1) and so are thermodynamically impossible. Equation (3) is, however, sufficient immediately to prove that if one component of a binary mixture shows positive deviations ($\ln f_1 > 0$) *over the whole range of compositions* then the other component cannot show negative deviations ($\ln f_2 < 0$) *over the whole range of compositions*, and conversely. No other general restriction on the signs of $\ln f_1$ and $\ln f_2$ can be derived from equation (1).

There remain, in addition to the well-known cases of deviations everywhere positive (or negative) for both components, possible cases in which $\ln f$ changes sign for one or both components between $x = 0$ and $x = 1$. For brevity we shall confine this discussion to kinds of behavior which are not only thermodynamically possible but have actually been observed. In none of these does $\ln f$ change sign more than once for each component.

The excess Gibbs function G^E is defined as the excess of the increase of the Gibbs function on mixing over that for an ideal mixture, and is related (*4*) to the activity coefficients by the equations

$$G^E/RT = (1 - x) \ln f_1 + x \ln f_2 \qquad (4)$$

$$\ln f_1 = (G^E/RT) - xd(G^E/RT)/dx \qquad (5)$$

$$\ln f_2 = (G^E/RT) + (1 - x)d(G^E/RT)/dx \qquad (6)$$

Whereas the composition dependence of $\ln f_1$ and $\ln f_2$ must be such as to satisfy equation (1) the only restriction on the composition dependence of G^E is that G^E shall be zero at $x = 0$ and at $x = 1$. Subject to that restriction any expression for G^E as a function of x will lead to thermodynamically possible activity coefficients by use of equations (5) and (6) since these equations satisfy the Duhem-Margules relation identically.

For the purpose of illustrating unusual kinds of deviations from Raoult's law by specific examples we shall use as a general expression for G^E the series

$$G^E/RT = x(1 - x)\{A + B(1 - 2x) + C(1 - 2x)^2 + \ldots\} \qquad (7)$$

which has often been used (*5, 2, 6*) to fit experimental results, and it will be sufficient for our purpose if we retain only the first three terms. Using equations (5) and (6) with (7) we then obtain for the activity coefficients

$$\ln f_1 = x^2\{(A + 3B + 5C) - (4B + 16C)x + 12Cx^2\} \qquad (8)$$

$$\ln f_2 = (1 - x)^2\{A + B + C) - (4B + 8C)x + 12Cx^2\} \qquad (9)$$

We shall now consider some special cases of equations (7), (8), and (9), first dealing briefly with the well-known cases of *ideal* and of *regular* or *simple* (*4*) mixtures, and then going on to give illustrative examples chosen for their mathematical simplicity, of more unusual but no less thermodynamically possible kinds of behavior.

Case I

The equations for an *ideal* mixture can be obtained if we put $A = B = C = 0$ in equations (7) to (9) so that

Suggestions of material suitable for this column and guest columns suitable for publication directly are eagerly solicited. They should be sent with as many details as possible, and particularly with references to modern textbooks, to Karol J. Mysels, Department of Chemistry, University of Southern California, Los Angeles 7, California.

[1] Since the purpose of this column is to prevent the spread and continuation of errors and not the evaluation of individual texts, the source of errors discussed will not be cited. In order to be presented an error must occur in at least two independent recent standard books.

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$G^E/RT = 0$ $\ln f_1 = 0$ $\ln f_2 = 0$

(An ideal mixture is thus defined by the equation $G^E = 0$. A mixture which obeys Raoult's law is strictly defined by the relations

$$p_1 = (1 - x)p_1^0 \text{ and } p_2 = xp_2^0$$

We remind the reader that we have ignored any distinction between partial pressure ratios and fugacity ratios, and that this is equivalent to ignoring the distinction between an ideal mixture and one which obeys Raoult's law. Our discussion therefore applies strictly to deviations from ideality rather than to deviations from Raoult's law, but the distinction will usually be unimportant.)

Partial pressures for an ideal mixture are shown as broken straight lines in all the following diagrams of the partial pressures of nonideal mixtures.

Case II

The equations for *regular* or *simple* (*4*) mixtures can be obtained if we put $B = C = 0$ in equations (7) to (9). We then obtain

$$G^E/RT = Ax(1 - x) \qquad \ln f_1 = Ax^2 \qquad \ln f_2 = A(1 - x)^2$$

As examples of the behavior of regular mixtures plots of G^E/RT, $\ln f_1$, and $\ln f_2$, and of p_1/p_1° and p_2/p_2° are shown for $A = 1$ (positive deviations from Raoult's law) in Figure 1, and for $A = -1$ (negative deviations from Raoult's law) in Figure 2.

Figure 1. Case IIa: $A = 1, B = C = 0$.

Figure 2. Case IIb: $A = -1, B = C = 0$.

Case III

One kind of unusual behavior can be illustrated if we put $B = -A$ and $C = 0$ in equations (7) to (9). We then obtain

$$G^E/RT = 2Ax^2(1 - x)$$
$$\ln f_1 = 2Ax^2(2x - 1) \quad \ln f_2 = 4A(1 - x)^2x$$

Examples of this kind of behavior are shown for $A = 1$ in Figure 3 and for $A = -1$ in Figure 4.

Mixtures of ethanol and chloroform at 35°C (*7*) give deviations from Raoult's law like those of case III*a* (Fig. 3). So do solid solutions of silver chloride and sodium chloride at 150°C (*8*), the deviations for this pair being large enough to cause a region of partial miscibility. Mixtures of pyridine and water, which according to von Zawidski (*9*) behave like case III*a*, have since been shown (*10*), however, to give deviations which are everywhere positive like case II*a* (Fig. 1).

Mixtures of nitromethane and acetone at 45°C have recently been shown (*11*) to behave like case III*b* (Fig. 4). Liquid mixtures of thallium and mercury at 325°C (*12*), cadmium and antimony at 480°C (*13*), zinc and antimony at 550°C (*14*), and potassium and mercury at 275°C and 325°C (*15*), and solid solutions of lead bromide and lead chloride at 200°C (*16*), have also been shown to behave like case III*b* (Fig. 4).

Figure 3. Case IIIa: $A = 1, B = -1, C = 0$.

Figure 4. Case IIIb: $A = -1, B = 1, C = 0$.

Case IV

Another kind of unusual behavior can be illustrated if we put $A = 0$ and $C = 0$ in equations (7) to (9). We then obtain

$$G^E/RT = Bx(1 - x)(1 - 2x)$$
$$\ln f_1 = Bx^2(3 - 4x) \quad \ln f_2 = B(1 - x)^2(1 - 4x)$$

An example of this kind of behavior is shown for $B = 1$ in Figure 5.

Solid solutions of *p*-dichlorobenzene and *p*-dibromobenzene at 50°C (*17*) have recently been shown to behave like case IV. The author knows of no other example.

Case V

Finally, yet another kind of unusual behavior can be illustrated if we put $B = 0$ and $C = -A$ in equations (7) to (9). We then obtain

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$G^E/RT = 4Ax^2(1 - x)$$
$$\ln f_1 = 4Ax^2(1 - x)(3x - 1) \ln f_2 = 4A(1 - x)^2x(2 - 3x)$$

Examples of this kind of behavior are shown for $A = 1$ in Figure 6 and for $A = -1$ in Figure 7.

Mixtures of benzene and bromobenzene at 80°C (*18*) are nearly ideal but have nevertheless been shown to behave like case V*a* (Fig. 6). Liquid mixtures of cadmium and potassium at 475°C (*19*) also behave like case V*a* (Fig. 6), the deviations for this pair being large enough to cause a region of partial miscibility.

Liquid mixtures of bismuth and cadmium at 431°, 477°, and 533°C (*20*) and at 500°C (*21*), and of lead and thallium at 438°C (*22*) have been shown to behave like case V*b* (Fig. 7).

It was shown by Dolezalek (*23*) that deviations from Raoult's law which are everywhere negative (case II*b* (Fig. 2); for example chloroform and ether) can be ascribed to the formation of a 1:1 compound in equilibrium with the parent substances, if it is assumed that the three species together form a ternary ideal mixture. Since then it has been commonly but wrongly supposed that "compound formation always leads to negative deviations from Raoult's law." In fact it has been shown (*24, 25*) that while that statement is true for 1:1 compounds, the formation of any compound *other* than 1:1 always leads to deviations which change sign for one or both of the components. For example the formation of a 1:2 compound leads to behavior like case III*b* (Fig. 4). The formation of both 1:1 and 1:2 compounds in the same mixture can lead either to behavior like case II*b* (Fig. 2) (deviations everywhere negative), or to behavior like case III*b* (Fig. 4) (deviations change sign for component 1), according to the relative amounts formed of the two compounds. Mixtures of chloroform and dioxane which probably form both 1:1 and 1:2 compounds turned out (*26*) to behave like case II*b* (Fig. 2), in spite of the author's hope that they might behave like case III*b* (Fig. 4) and so be another example of unusual behavior.

Apart from the advantages of not telling lies in the lecture room the author has found that these examples of unusual behavior provide a useful way of familiarizing the student with the Duhem–Margules relation and its consequences and applications. Calculations, with various chosen values for the equilibrium constants, of the properties of mixtures in which one or two compounds are formed, have proved a useful exercise for advanced students.

Figure 5. Case IV: $A = 0, B = 1, C = 0$.

Figure 6. Case V*a*: $A = 0, B = 1, C = -1$.

Figure 7. Case V*b*: $A = -1, B = 0, C = 1$.

Potentiometric Titration Curves for Simple Ion Combination Reactions

A simple ion combination reaction is one in which the slightly dissociated (either slightly ionized or slightly soluble) product of the chemical reaction is composed of two symmetrical charge type ions.

The rigorously derived (from considerations of electroneutrality and/or material balance) equation which theoretically characterizes a potentiometric titration curve obtained for a simple ion combination reaction is a quadratic with respect to the concentration of either ion involved in the reaction (*1*, *2*). Obviously, an exact solution for the concentration of interest, C, may be obtained via the quadratic formula; subsequently, the negative logarithm of the concentration, pC, may then be obtained (*2*).

Alternatively, one may obtain pC directly, by recognizing that the logarithm of the solution to any quadratic equation may be expressed in terms of the inverse hyperbolic sine of a "titration function" which is dependent upon the fraction titrated, the initial concentration of the species to be titrated, and the dissociation constant characteristic of the reaction product which results from the ion combination. Account may be easily taken of the dilution which occurs during the titration.

This form of the exact equation is not really new, although it does not appear to have ever been considered as providing a relatively easy method for the rigorous calculation of these titration curves, under any conditions. It has, however, been used as a basis for determining endpoints, by Cavanagh (*3*) and Fortuin (*4*).

Investigation of this equation allows one to determine the region, in terms of the "fraction titrated" parameter, f, wherein the exact equation must be used. Outside of this region, the rigorously derived equation reduces to the more commonly used expressions.

It should be remembered that alternatively, a rigorous calculation of a titration curve can always be accomplished by considering the concentration of one of the ions, rather than the fraction titrated, to be the independent variable. Such a procedure is always applicable, and especially useful for titrations which result in the formation of unsymmetrical reaction products, as has been recently emphasized by Bishop (*5*). The equation which will be discussed in this article is applicable only to the formation of a symmetrical reaction product.

The Exact Equation

Consider the simple ion combination reaction:

$$\mathrm{M} + \mathrm{X} = \mathrm{MX} \tag{1}$$

where M and X represent a cation and anion, respectively; the equal in magnitude, but opposite in sign, charges being omitted. MX is the slightly dissociated product for which:

$$K = [\mathrm{M}][\mathrm{X}] \tag{2}$$

where the brackets represent molar concentrations of the indicated species, and K is a concentration (or formal) equilibrium constant, rather than a true thermodynamic one. However, under the usual conditions, this concentration constant remains approximately constant, at least in the vicinity of the equivalence point, because of the approximate constancy of the ionic strength in this region. The smaller the amount of dilution that occurs, the more constant will be the ionic strength. The variation of ionic strength during the entire titration can always be virtually eliminated by use of a large concentration of inert electrolyte.

The complete chemical equation for the titration may be written as:

$$\mathrm{MB} + \mathrm{CX} = \mathrm{MX} + \mathrm{CB}$$

where B and C are the accompanying anion and cation respectively, of M and X.

Therefore, the condition of electroneutrality may be written as:

$$[\mathrm{M}] + [\mathrm{C}] = [\mathrm{X}] + [\mathrm{B}] \tag{3}$$

If we consider that we are titrating V° milliliters of a solution of CX of original molar concentration C°, then the molar concentrations of B and C, at any fraction titrated, f, are:

$$[\mathrm{B}] = \frac{C^\circ V^\circ}{V^\circ + V} f \tag{4}$$

$$[\mathrm{C}] = \frac{C^\circ V^\circ}{V^\circ + V} \tag{5}$$

where we assume the volumes to be additive, and where V is the volume, in milliliters, of the added titrant, at the corresponding fraction titrated, f.

By definition:

$$f = V/q \tag{6}$$

where q is the volume of titrant necessary to reach the equivalence point, at which:

$$C^\circ V^\circ = C_T q \tag{7}$$

where C_T is the molar concentration of the titrant.

Rewriting $V^\circ/(V + V^\circ)$ as $1/(1 + V/V^\circ)$ and recognizing that $V/V^\circ = (q/V^\circ)\,(V/q)$, we then may solve equation (7) for q/V° and write:

$$\frac{V^\circ}{V + V^\circ} = \frac{1}{1 + rf} \tag{8}$$

if we define r as:

$$r = C^\circ/C_T \tag{9}$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

where r is an auxiliary parameter. f may be considered to be the primary parameter.

Substitution of equation (8) and of [X] from equation (2) into equation (3), yields:

$$[\mathrm{M}] + \frac{C^\circ}{1+rf} = \frac{K}{[\mathrm{M}]} + \frac{C^\circ f}{1+rf} \qquad (10)$$

Two comments should be made concerning equation (10). First, it applies for all values of f (including zero) only for acid-base neutralizations, in which case MX represents HOH; for precipitation titrations, equation (10) is valid only for a nonzero value of f because equation (2) does not apply until some precipitate is formed. Second, if we neglect dilution (i.e., $r = 0$) we obtain the usual approximate equation for electroneutrality. Our definition of the auxiliary parameter, r, is thus logical because the greater the concentration of titrant relative to the concentration of the species being titrated, the smaller is the avlue of r.

Rearrangement of equation (10) to:

$$\frac{[\mathrm{M}]}{K^{1/2}} - \frac{K^{1/2}}{[\mathrm{M}]} = \frac{C^\circ(f-1)}{K^{1/2}(1+rf)}$$

and recognition of the following identity:[1]

$$\frac{[M]}{K^{1/2}} - \frac{K^{1/2}}{[\mathrm{M}]} = \exp\left(\ln\frac{[\mathrm{M}]}{K^{1/2}}\right) - \exp\left(-\ln\frac{[\mathrm{M}]}{K^{1/2}}\right)$$

$$= 2\sinh\left(\ln\frac{[\mathrm{M}]}{K^{1/2}}\right)$$

yields:

$$2\sinh\left(\ln\frac{[\mathrm{M}]}{K^{1/2}}\right) = \frac{C^\circ(f-1)}{K^{1/2}(1+rf)}$$

or:

$$\ln[\mathrm{M}] - \frac{1}{2}\ln K = \sinh^{-1}\frac{C^\circ(f-1)}{2K^{1/2}(1+rf)}$$

where $\sinh^{-1}$ represents the inverse hyperbolic sine. After conversion from natural logarithms we obtain:[2]

$$p\mathrm{M} = \frac{1}{2}pK - \frac{1}{2.303}\sinh^{-1}\frac{C^\circ(f-1)}{2K^{1/2}(1+rf)} \qquad (11)$$

where, as usual, $p\mathrm{M} = -\log[\mathrm{M}]$ and $pK = -\log K$. Making use of the identity: $-\sinh^{-1}x = \sinh^{-1}-x$, we may also write equation (11) as:

$$p\mathrm{M} = \frac{1}{2}pK + \frac{1}{2.303}\sinh^{-1}\frac{C^\circ(1-f)}{2K^{1/2}(1+rf)} \qquad (12)$$

or:

$$p\mathrm{M} = \frac{1}{2}pK + \frac{1}{2.303}\sinh^{-1}F$$

where the titration function, F, is equal to

$$C^\circ(1-f)/2K^{1/2}(1+rf)$$

It is important to emphasize that $p\mathrm{M}$ is symmetrical with respect to F, but F is not symmetrical with respect to f unless dilution is neglected ($r = 0$); thus, in general, $p\mathrm{M}$ is not symmetrical with respect to f. The significance of this is that the theoretically calculated titration curve, which takes account of dilution, is slightly asymmetrical, and therefore the endpoint and equivalence point will not coincide (*6*).

Equations (11) and (12) are equivalent, but prior to the equivalence point it is more convenient to use the latter.

From either equation (11) or (12), it is easily seen that $p\mathrm{M} = (\frac{1}{2})pK$ at $f = 1$, because $\sinh^{-1} 0 = 0$. It is also obvious (from either equation (10) or (12)) that the result of taking the dilution into account is to yield at any particular value of f prior to equivalence, a smaller value of $p\mathrm{M}$ than if dilution is neglected, while (from equation (10) or (11)) at any value of f beyond equivalence the value of $p\mathrm{M}$ is larger than it would be if dilution is neglected. In other words, the calculated curve which neglects dilution intersects with the one which does not at $f = 1$, as it must, because $p\mathrm{M}$ at the equivalence point is independent of dilution and dependent only upon the magnitude of the equilibrium constant.

Approximate Forms of the Exact Equation

For values of F such that $F^2 \gg 1$, i.e., F^2 much greater than unity: $\sinh^{-1} F \simeq \ln 2F$, so that equation (12) may be written as:

$$p\mathrm{M} = -\log\frac{K(1+rf)}{C^\circ(1-f)} \qquad (13)$$

for values of f such that:

$$f \ll \frac{1 - 2K^{1/2}/C^\circ}{1 + 2rK^{1/2}/C^\circ} \qquad (14)$$

Equation (13) is the usual approximate equation that applies before the equivalence point.

If equation (11) is written as:

$$p\mathrm{M} = \frac{1}{2}pK - \frac{1}{2.303}\sinh^{-1}\mathrm{G}$$

then for $G^2 \gg 1$: $\sinh^{-1} G \simeq \ln 2G$, so that equation (11) may be written as:

$$p\mathrm{M} = -\log\frac{C^\circ(f-1)}{1+rf} \qquad (15)$$

for values of f such that:

$$f \gg \frac{1 + 2K^{1/2}/C^\circ}{1 - 2K^{1/2}/C^\circ} \qquad (16)$$

Equation (15) is the familiar expression for the region beyond the equivalence point.

Therefore the exact equation (either equation (11) or (12)) must be used in the region:

$$\frac{1 + 2K^{1/2}/C^\circ}{1 - 2rK^{1/2}/C^\circ} \gg f \gg \frac{1 - 2K^{1/2}/C^\circ}{1 + 2rK^{1/2}/C^\circ} \qquad (17)$$

It is seen that the effect of a nonzero value of r is to slightly extend the region within which we must use the exact equation; also, the portion of the region subsequent to equivalence is somewhat larger in magnitude than that prior to equivalence, unless $r = 0$.

The magnitude of the region defined by equation (17) depends on the value of the equilibrium constant K, the initial concentration C°, and the dilution parameter r. Indeed, it is the ratio $K^{1/2}/C^\circ$, which is of interest rather than the absolute value of either term comprising the ratio.[3] The region within which we can use the customary approximate expressions is increased when

[1] Exp $x = e^x$, $\sinh x = \frac{1}{2}[\exp(x) - \exp(-x)]$.

[2] For the reverse titration, i.e., titration of MB by CX, we obtain:

$$pM = \frac{1}{2}pK - \frac{1}{2.303}\sinh^{-1}\frac{C^\circ(1-f)}{2K^{1/2}(1+rf)}$$

[3] Note that $K^{1/2}$ is the concentration of X at $f = 1$ while C° is its initial concentration, at $f = 0$.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

the initial concentration is increased, the equilibrium constant is decreased, and, or, the dilution parameter is decreased.

Error in Using the Approximate Instead of the Exact Equation

Of considerable interest is the error in pM, ΔpM, which is incurred by the use of the approximate rather than the exact equations.

Prior to equivalence, the value of pM calculated from equation (12) will be greater than that obtained from equation (13); subsequent to $f = 1$, the rigorously calculated value of pM (from equation (11)) will be smaller than that obtained from the approximate formula (equation (15)).[4] At $f = 1$, neither of the approximate equations applies but $p\mathrm{M} = (1/2)\, pK$; thus, at the equivalence point, the theoretical curve calculated from the approximate equations intersects with that calculated from the exact equations.

Let us consider the region prior to equivalence. Defining ΔpM so as to be positive, we may subtract equation (13) from equation (12), to obtain:

$$\Delta p\mathrm{M} = \frac{1}{2}\, pK + \frac{1}{2.303} \sinh^{-1} F + \frac{1}{2.303} \ln \frac{K(1 + rf)}{C^\circ(1 - f)}$$

However,

$$K(1 + rf)/C^\circ(1 - f) = K^{1/2}/2F$$

so by substitution of $K^{1/2}/2F$ into the argument of the natural logarithm, we obtain:

$$\Delta p\mathrm{M} = \frac{1}{2.303} \left[\sinh^{-1} F - \ln 2F\right] \qquad (18)$$

from which it is easy to calculate the error in pM corresponding to any selected value of F. More enlightening is the investigation of the minimum value, a, that F must possess so that ΔpM does not exceed some selected value, b. As equation (18) cannot be solved explicitly for F one must substitute various values for F until one attains the desired value of ΔpM. An extensive table of inverse hyperbolic sines is useful for this purpose (7). The results of these calculations are presented in Table 1 for some representative values of ΔpM.

[4] This can be easily seen because

$$\sinh^{-1} x = \ln 2x + \frac{1}{4x^2} - \ldots$$

consideration of equation (10) leads to the same conclusion.

It is interesting to note that though it is usually thought that F must exceed unity in order to transform the exact equation into the more usual approximate one; in reality, to make an error no greater than 0.10 in the calculation of pM, F need only equal or exceed 0.875. Of course, for values of F less than unity, $\sinh^{-1} F \sim F$ *is a better approximation*, and indeed ΔpM is then reduced to 0.04 for $F = 0.875$.

To find the value of f corresponding to any value of a in Table 1, we use:

$$f \leq \frac{1 - 2aK^{1/2}/C^\circ}{1 + 2arK^{1/2}/C^\circ} \qquad (19)$$

which is derived directly from $F \geq a$. Thus, to make an error of b (or less) in the calculation of pM, we cannot use the approximate equation for any value of f greater than that obtained from equation (19).

Until now we have only considered the region prior to equivalence. However, as previously discussed, pM is symmetrical with respect to F. Therefore, subsequent to equivalence, if ΔpM is still defined as the difference between the approximate (equation (15)) and the exact (equation (11)) equations:

$$\Delta p\mathrm{M} = \frac{1}{2.303} \left[\ln 2G - \sinh^{-1} G\right],$$

where $G = C^\circ (f - 1)/2K^{1/2} (1 + r f)$. Use of the values of a found in Table 1, for G, will result in the same values of b listed there except prefixed by a negative sign.

Table 1. Minimum Values of F^a For Selected Values of ΔpM

a	b
0.875	0.1000
1.35	0.0500
2.25	0.0200
3.23	0.0100

[a] $F \geq a$ for $\Delta p\mathrm{M} \leq b$.

In other words, the exact equation must be used in the region:

$$\frac{1 + 2aK^{1/2}/C^\circ}{1 - 2arK^{1/2}/C^\circ} \geq f \geq \frac{1 - 2aK^{1/2}/C^\circ}{1 + 2arK^{1/2}/C^\circ} \qquad (20)$$

if ΔpM is not to exceed $\pm\, b$; the corresponding value of a being obtained from Table 1 or a similar type of table. For convenience, we may write equation (20) as:

$$f_2 \geq f \geq f_1 \qquad (21)$$

Values of f_1 and f_2 for various values of $K^{1/2}/C^\circ$ are presented in Table 2; $r = 0$ corresponds to neglect of

Table 2. Values of f_1 and f_2 Defined by Equation (21)

dilution; $r = 1$ applies to a titration in which the concentration of the titrant is equal to the original concentration of the species being titrated.

It is evident that for $r \leq 1$, the approximate equation can be used, with an error not exceeding 0.0100 in pM, even at 0.1% titrated prior or subsequent to equivalence, as long as $C^\circ/K^{1/2}$ exceeds 10^4. For acid-base neutralizations, this corresponds to a pH difference of 4.00 units between the initial pH and that at equivalence; thus C° must equal or exceed 1.00×10^{-3} M.[5]

It should be emphasized that because pM is logarithmically related to [M], a relatively large error in [M], results however in a considerably smaller error in pM. This somewhat mathematically fortuitous result does not excuse a student from being able to calculate [M], to as great an accuracy as may be desired, by use of the appropriate formula. However, recognition of this relationship may save considerable time if only a calculation of a titration curve (pM versus f) is required.

A brief consideration of this relationship follows.

Prior to equivalence, the approximate value of [M] from equation (13) is greater than that calculated from the exact equation (12); i.e., $p\mathrm{M}_{\mathrm{approx}} < p\mathrm{M}_{\mathrm{exact}}$.

Thus, if the error in the calculation of [M] is $100\,E_{\mathrm{M}}\%$:

$$E_{\mathrm{M}} = \frac{[\mathrm{M}]_{\mathrm{approx}} - [\mathrm{M}]_{\mathrm{exact}}}{[\mathrm{M}]_{\mathrm{exact}}} = \frac{[\mathrm{M}]_{\mathrm{approx}}}{[\mathrm{M}]_{\mathrm{exact}}} - 1 \qquad (22)$$

From equation (13):

$$[\mathrm{M}]_{\mathrm{approx}} = \frac{K(1 + rf)}{C^\circ(1 - f)} = \frac{K^{1/2}}{2F}$$

and from equation (12):

$$[\mathrm{M}]_{\mathrm{exact}} = K^{1/2} \exp\left[-\sinh^{-1} F\right]$$

so that equation (22) may be written as:

$$E_{\mathrm{M}} = \frac{\exp\left[\sinh^{-1} F\right]}{2F} - 1 \qquad (23)$$

In Table 3 are presented the minimum values that F must possess in order that E_{M} does not exceed the indicated error. Through the use of equation (19) one may estimate the region of f values wherein the exact equation must be employed to obtain [M] to any desired accuracy.[6]

From equation (22), we obtain:

$$\Delta p\mathrm{M} = \log(1 + E_{\mathrm{M}}) \qquad (24)$$

which reflects the lesser dependence on E_{M}, of the accuracy of pM than that of [M]. A ten per cent error in [M], i.e., $E_{\mathrm{M}} = 0.10$, results in only an error 0.04 units in pM; a five per cent error in [M] yields only an error of 0.02 in pM. Thus to calculate pM to within 0.10 unit, it is only required that $E_{\mathrm{M}} \leq 0.26$.

[5] $$p\mathrm{H}_{f=0} - p\mathrm{H}_{f=1} = \frac{1}{2.303}\sinh^{-1} C^\circ/2K^{1/2} \simeq \log C^\circ/K^{1/2}$$

for $C^\circ/K^{1/2} \gg 1$; $K_w^{1/2} = 1.00 \times 10^{-7}$ at 25° C.

[6] For values of

$$f > 1:\ E'_{\mathrm{M}} = \frac{-E_{\mathrm{M}}}{1 + E_{\mathrm{M}}} \text{ where } E'_{\mathrm{M}}$$

is defined by equation (22), but now only applies subsequent to equivalence, and E_{M} is obtained from Table 3.

Table 3. Minimum Values for F for Selected Values of E_{M}

F	E_{M}
1.51	0.100
2.18	0.0500
3.50	0.0200
4.98	0.0100
7.04	0.0050
11.1	0.0020
15.8	0.0010

Summary

Examination has been made of the properties of the rigorously derived equation which is applicable to the calculation of a potentiometric titration curve for a simple ion combination reaction. Under appropriate conditions, expressed in terms of the fraction titrated, the customary approximate equations may be used.

The presentation of the exact equation emphasizes the principle that the complete titration curve may be represented by a single function, i.e., the curve is continuous. Under conditions where the approximate equations cannot be accurately used, the calculation of pM is nevertheless relatively easy as compared to first obtaining [M] by use of the quadratic formula. The use of tables of the inverse hyperbolic sine should present no difficulties and allows the student to become familiar with some properties of hyperbolic functions.

Finally, a brief consideration has been made of the relationship between the error in [M] and in pM.

Tangent-Sphere Models of Molecules

II. Uses in teaching

Chemistry witnessed this past year a striking event. Synthesized for the first time were compounds of the "inert" gases. Like most events in chemistry, this event was exciting in proportion to the degree that it was unexpected. It served, thus, as a dramatic reminder of a fundamental fact: chemistry is (still) an experimental science. Even today, for example, several decades after the advent of quantum mechanics, chemistry does not possess a satisfactory mathematical theory of systems more complex than the isolated hydrogen molecule. Several reasons for this were examined in Part I. It was concluded there that possibly the Pauli Principle is more important than previously supposed. To explore the chemical implications of this possibility, there was introduced a model in which tangent-spheres were used to represent a combined atom's valence-shell electron pairs—or, perhaps more properly, the "Fermi holes" associated with these electron pairs. This model, it was seen, is capable of representing the salient stereochemical features of conventional, covalent bonds. It is found that the model can also be used to represent highly strained bonds and multicentered bonds, atoms with expanded octets and atoms with contracted octets, intermolecular interactions and intramolecular interactions, and the effects of electronegative groups, lone pairs, and multiple bonds upon molecular geometry, bond properties, and chemical reactivity. These uses of the models are described below, following a summary, in the first three sections, of model uses discussed previously in Part I.

Isomorphism with Valence-Bond Diagrams

Every line or pair of dots in the valence-bond representation of a molecule becomes in the model a sphere, and vice versa. In effect the model is a three-dimensional reconstruction of the two-dimensional valence-bond diagram.[1] Conversely, a valence-bond diagram may be viewed as a two-dimensional projection of a three-dimensional model in which (1) lines are used for protonated spheres (bonds to hydrogen atoms) and for spheres adjacent to two tetrahedral holes (the single bond in ethane, Fig. 5 (Part I), for example, and the components of the multiple bonds in ethylene and acetylene, Figs. 38 and 39); (2) dots are used for unprotonated spheres bordering on a single tetrahedral hole (lone pairs); and (3) letters (H, C, N, O, etc.) are used to indicate locations of protons and other more complex atomic cores.

Gross Details of Stereochemistry

One immediate consequence of the tangent-sphere model is the tetrahedral geometry about atoms involved in four single bonds (Figs. 3 and 5; also Figs. 8–15 (Part I)), the planar geometry about atoms involved in one double bond (Fig. 38), and the linear geometry about atoms involved in a triple bond (Fig. 39) or two double bonds (Fig. 21, Part I).

Finer Details of Stereochemistry

More subtile details of molecular conformation that can be illustrated and discussed with the aid of tangent-sphere models include: the staggered and eclipsed configurations of ethane; the *trans* and gauche conformers of *n*-butane; the equatorial and polar bonds and the chair and boat confomers of cyclohexane (and the more complex confomers of higher perhydroaromatics); the puckered cyclobutane ring; the orientation of groups adjacent to double bonds and the equilibrium shapes of such molecules as acetaldehyde and propylene, 1,3-butadiene, 1,3,5-hexatriene, and 1,3,5,7-cyclooctatetraene; and steric interactions in skew *n*-butane and such other molecules as 2-butene, the isomers of fluoro-propene, and the mono- and di-methyl substituted cyclohexanes (*20*, *21*).

Strained Bonds

Tangent-sphere models can be used to represent not only normal multiple bonds, Figures 38 and 39, but as well the strained, bent bonds in such molecules as cyclopropane, Figure 25, cyclopropene, Figure 26, and benzyne, Figure 27.

Multicentered Bonds (22)

The model of ethylene, Figure 38, can serve equally well as a model of B_2H_6, if one supposes that the heavy atoms in the two tetrahedral holes are boron atoms and that all six spheres are protonated. The relation of

A preliminary account of this work was presented at the Gordon Research Conference in Inorganic Chemistry, New Hampton, N. H., August 6–10, 1962.

This study was supported by a grant of a Faculty Summer Research Committee Appointment from the Graduate School of the University of Minnesota, by a du Pont Grant-in-Aid to the Department of Chemistry of the University of Minnesota, and in part by the National Science Foundation. This support is gratefully acknowledged.

[1] This is an effective way to introduce the models to beginning students who already have had some experience with valence-bond diagrams. The models may be viewed as adding literally another dimension to their knowledge of stereochemistry. With very young students, however, we suspect it might be easier and more "natural" to introduce the models first and their two-dimensional projection diagrams second.

Editor's Note: The first part of this paper appeared in the September issue of This Journal, 40, 446 (1963). Literature citations and figures are numbered consecutively for the whole paper; citations 1–21 and Figures 1–24 appeared in the first part.

Figure 25. Tangent-sphere model of cyclopropane. Dotted lines represent spheres whose centers lie behind the plane of the paper, heavy lines spheres whose centers lie above this plane. The inner three circles represent carbon-carbon bonds, the outer six carbon-hydrogen bonds. At the right is the corresponding valence-bond diagram.

Figure 26. Tangent-sphere model and valence-bond diagram of cyclopropene. Clockwise from 12 o'clock the circles represent C═C (top center), C—H, C—C, CH_2 (bottom center), C—C, C—H.

Figure 27. Tangent-sphere model and valence-bond diagram of the triple-bond representation of benzyne. The model is formed from fragments of five close-packed layers containing, from top to bottom (or bottom to top), 1, 4, 4, 4, and 1 spheres. Only the six outer tetrahedral holes (two on the right, two on the left, and one each at the top and bottom) are occupied by carbon nuclei. It may be significant to note that it is apparently impossible to construct an equal-sphere-size model of a six-membered ring containing four double bonds.

Figure 28. Tangent-sphere model and valence-bond diagram of B_4H_{10}. The model's four tetrahedral holes, which lie N, E, S, and W from the center, correspond to the gaps in the valence-bond diagram at the right. The six stippled circles represent two-centered boron-hydrogen bonds, the four open ones three-centered boron-hydrogen-boron bonds. The cross-hatched circle represents the two-centered boron-boron bond.

this structure to the ethylene structure may be illustrated in two-dimensions as follows (*cf.*, ref. (*31*), p. 306).

In a similar manner the valence-bond representation of B_4H_{10} can be derived from the following (probably hypothetical (*23*)) bicyclic structure of the dimer of nitric oxide.

The corresponding tangent-sphere representation of B_4H_{10} is illustrated in Figure 28. The B_4H_{10} structure contains four three-centered boron-hydrogen-boron bonds.[2]

Addition of a trigonal set, representing the ion CH_3^+, to one component of the double bond of ethylene converts the model shown in Figure 38 into the tangent-sphere representation of a non-classical carbonium ion whose valence-bond structure as shown below and in Figure 29 contains one three-centered carbon-carbon-carbon bond.

This three-centered bond is similar to the three-centered aluminum-carbon-aluminum bonds in the dimer of aluminum trimethyl and to the three-centered boron-boron-boron bonds in B_4Cl_4.

Figure 29. Tangent-sphere model of the non-classical carbonium ion $C_3H_7^+$. In the superimposed valence-bond diagram the three-centered carbon-carbon-carbon bond is indicated by three intersecting lines, which form an inverted "Y." In the literature this bond is usually indicated by a dashed triangle. Transition from this bridged structure to the classical structure $CH_3CH_2H_2^+$ can be visualized as occurring through a (perhaps solvent, S_N2-initiated) downward motion against the carbon-carbon two-centered bond (the bottom-most sphere) of the two protonated spheres of the methylene group on the right, or the one on the left. Formation of the secondary carbonium ion $CH_3CH^+CH_3$ from the primary carbonium ion $CH_3CH_2CH_2^+$ can be visualized as occurring in two steps of the type just described through the intermediate formation of a three-centered carbon-hydrogen-carbon bond.

Figure 30. Two views of the bonding pairs in B_4Cl_4. The four stippled spheres represent two-centered boron-chlorine bonds, the four open spheres three-centered boron-boron-boron bonds. Each boron atom has in its valence shell four pairs: one boron-chlorine bond and three boron-boron-boron bonds. Not shown are the unshared pairs on the chlorine atoms.

The tangent-sphere representation of B_4Cl_4, excluding the lone pairs on the chlorine atoms, contains an inner tetrahedral set formed from four mutually tangent spheres. On each of the four trigonal faces of this tetrahedron rests another sphere (Fig. 30). Created in this way are four symmetrically placed tetrahedral holes. These holes contain the boron nuclei and their inner-shell electrons. The four outer spheres represent two-centered boron-chlorine bonds. The four inner

spheres represent three-centered boron-hydrogen-boron bonds.

Most of the known boron hydrides can be represented by tangent-sphere models. Figure 31 is an illustration of a symmetrical structure for the unknown compound B_9H_{15}. The presumed instability of this structure probably arises in part from the close approach to each other of the top three hydrogen atoms.

The tangent-sphere representation of lithium hydride is interesting to consider. It consists of a cubic-close-packed array of spheres, each sphere of which represents an electron pair and at whose center is a

Figure 31. Tangent-sphere model and valence-bond diagram of a hypothetical structure for B_9H_{15}. Open spheres are protonated. The three at the top and the six outer ones at the bottom represent two-centered boron-hydrogen bonds; the six inner open spheres represent three-centered boron-hydrogen-boron bonds. Stippled spheres represent two-centered boron-boron bonds, black ones three-centered boron-boron-boron bonds. For a leading reference on the boron hydrides, see Hoffmann and Lipscomb, *J. Chem. Phys.*, 37, 2872 (1962).

proton. These protonated spheres represent the hydride ions. Surrounding each hydride ion are six lithium ions in the octahedral holes of the protonated electron-pair lattice.[3] The hydride ions represent, therefore, seven-centered lithium-lithium-lithium-lithium-lithium-lithium-hydrogen bonds. This result is not entirely surprising. Starting with the neon atom and moving to the left through the hydrides HF, H_2O, NH_3, CH_4, B_2H_6, and $(BeH_2)_n$, one finds that the number of electron pairs in one-centered orbitals (the unshared pairs) steadily decreases; the figures are, respectively, 4, 3, 2, 1, 0, 0, 0. The corresponding figures for the number of electron pairs per heavy atom in two- and three-centered orbitals are, respectively, 0, 1, 2, 3, 4, 2, 0 and 0, 0, 0, 0, 0, 1, 2. The trend seems clear. In moving toward lithium hydride increasing use is made of multicentered orbitals.

Alternatively, one may note that the core radius (0.60 Å) of lithium is much larger than the core radii of the other first-row elements (0.15, 0.11, 0.09, and 0.07, respectively, for carbon, nitrogen, oxygen, and fluorine (Pauling)). In this respect, lithium is like the second-row elements—particularly magnesium (core radius 0.65 Å)—where, so to speak, the valence-shell electrons touch the atomic cores before they touch each other and where, as a result, expanded octets are not uncommon. In the case of lithium, however, the formal charge on the atom would generally be excessive when its valence-shell contains six electron pairs unless, as in lithium hydride, these electrons are widely shared.

[3] Each Li^+ ion consists of a nucleus, charge $+3e$, and a $1s^2$ shell (not mentioned above) whose volume is about 3% of the volume of an H^- ion.

Electron Configuration About Atoms That Do Not Obey the Octet Rule

From the standpoint of the tangent-sphere model, the stereochemical features listed under "Gross Details" are an immediate consequence of the coordination by an atom of four localized electron pairs. The examples so far discussed all fall into this category. Figure 32 illustrates the useful fact that the tangent-sphere model can also be used to obtain the orbital configuration about atoms with electron-pair coordination numbers 1(H^-, He, Li^+), 2(BeH_2), 3(BH_3, CH_3^+, CH_2 (singlet state)), 5(PCl_5, SF_4, ClF_3, XeF_2, I_3^-), and 6 (SF_6, NSF_3, BrF_5, XeF_4, ICl_4^-).

Figure 32. Summary of the stereochemistry about combined atoms for the electron-pair coordination numbers commonly encountered in practice. Coordination about an atomic core of one, two, three, four, five, or six localized electron pairs in the manner illustrated corresponds to the use, respectively, of the hybrid orbitals *s*, *sp*, sp^2, sp^3, dsp^3, or d^2sp^3.

Isoelectronic Molecules

The methane model, Figure 3 (Part I), may be thought of as representing also the electronic structure of ammonia and water. In the latter instances one or more of the valence-shell spheres would not be protonated. Calculations suggest that this does not greatly alter the effective size of a sphere (*16a*). Similarly, Figure 5 may be used to illustrate the electronic structures of ethane, methyl amine, methyl alcohol, methyl fluoride, hydrazine, hydroxyl amine, hydrogen peroxide, and so forth. It is interesting to note that the chlorine derivative of the recently reported (and probably planar) molecule XeF_4 (*24*) is isoelectronic with the well-known planar ion ICl_4^-. In the same sense, XeF_2 is equivalent to ICl_2^-.

Intermolecular Interactions

Inspection of the tangent-sphere models suggests that the interaction of an unshared pair on one molecule with the force field of a nucleus in another molecule should probably occur most readily off one of the external "pocket" sites in the second molecule. If the interaction between the attacking pair and the nucleus attacked is sufficiently strong, the nucleus may move from its normal position within its tetrahedral hole in the direction of the approaching lone pair on the nucleophilic reagent. This shift in nuclear position relative to the electron cloud of the system can be crudely summarized as follows.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Starter Kit
Digitized by Arya Samaj Foundation Chennai and eGangotri

The models thus provide a concrete and perhaps not altogether imprecise picture in three dimensions of that branch of two-dimensional pencil-and-paper chemistry that for want of a better term is often referred to as "arrow bending" or "curly arrow chemistry." Pictured in Figure 33 is the tangent-sphere representation of a conventional S_N2 displacement reaction.

The same form of pair-pocket interaction can be used to account for such facts as the structure of crystalline iodine and the structures of the iodine complexes of amines, ethers, and ketones (*25*); the presence of linear chains in crystalline halogen cyanides; the occurrence in the halogen cyanides as well as in certain other molecular crystals of abnormally short intermolecular contacts; and the shapes of the ions I_5^-, Figure 34, and I_8^{2-} (*26*).

Intramolecular Interactions

Strong interaction between an electron pair and an adjacent internal pocket may lead after a simple nuclear displacement of the type mentioned to the formation of a new chemical bond with simultaneous rupture of an old one, i.e., to *trans*-elimination. Weaker interactions of the same kind may manifest themselves as lengthened vicinal bonds (*27*) or, if the vicinal bond is one of the C-H bonds of a methyl group, to an apparent tilt of the methyl group's symmetry axis toward the electron pair (*28*), with a concomitant increase in the corresponding valence angle. (In dimethyl ether, for example, the COC angle is greater than tetrahedral.) In orbital language this interaction may be described as the overlap of an electron pair with the internal lobe of the antibonding orbital of a *trans*-oriented vicinal bond.[4]

[4] These conclusions are supported by the recent suggestion of N. Muller and D. Carr (*J. Phys. Chem.*, 67, 112 (1963)) that the most important single parameter influencing the magnitude of the spin-spin coupling constants between ^{19}F and directly bonded ^{13}C nuclei is the "degree of double character" of the C—F bond.

Many of the facts of structural chemistry cited above can be demonstrated at the cost of only a few cents with 12 small spheres preassembled as a tetrahedral group (called below "4"), a digonal group ("2"), and two trigonal groups ("3", "3"). From these four vest pocket-sized components can be assembled—with the aid of appropriate valence-bond diagrams and a little manual dexterity—models of the tangent-sphere representations of the families of isoelectronic structures that contain such molecules as methane (4), ethane (4+3), propane (4+3+3), ethylene (4+2 or 3+3), carbon dioxide (3+3+2), carbon suboxide (3+3+2+4), propylene (4+2+3), *cis*-and *trans*-2-butene (4+2+3+3), acetone (4+2+3+3), acetylene (3+2), diacetylene (3+2+4), cyclopropane (4+3+2), cyclopropene (3+3+2), and cyclobutane (4+3+3+2). The 12-sphere kit can also be used to illustrate such things as the digonal, trigonal, trigonal bypyramidal, and octahedral arrangements of electron pairs about atoms (Fig. 32);

Figure 34. Tangent-sphere representation of the pentaiodide ion. As the formulation $I^-(I_2)_2$ for this ion suggest, I_5^- may be viewed as the interaction of an iodide ion with two iodine molecules: I-I···I⁻···I-I. The dotted lines in this formulation of the complex represent interactions between electron pairs in the valence shell of the iodide ion (the stippled spheres above) with the external pockets of the iodine molecules. The solid lines represent the original, now slightly weakened iodine-iodine bonds within the iodine ligands (the black spheres above). Two such pair-pocket interactions (···) on the same tetrahedral donor atom (I^-) produce a non-linear, v-shaped complex. It is pictured above as seen from the open edge of the "v." Similar considerations apply to the ion I_8^{2-}, whose modified valence-bond representation is I-I···I⁻···I-I···I⁻···I-I

Figure 33. Tangent-sphere representation of a Walden inversion: the reaction $HO^- + H_3C—Cl = HO—CH_3 + Cl^-$. Stippled spheres represent O—H and C—H bonds, open spheres lone pairs. Cross-hatched spheres represent bonds between carbon and chlorine (stages 1 and 2) or carbon and oxygen (stages 4 and 5). The solid dot represents the carbon core. The dashed line through the methyl group indicates a plane through which the carbon core eventually passes. Stage 1: the reactants. Stage 2: backside attack on the methyl group by the hydroxide ion; the carbon core is beginning to move toward one of the previously unshared pairs on the oxygen atom. Stage 3: the transition state; this could also be a model of the triiodide ion, or of xenon difluoride. Stage 4: "mirror image" of stage 2; the carbon core is now more closely associated with the incoming pair on oxygen than with the outgoing pair on chlorine. Stage 5: the products.

the equilibrium conformation of methyl groups adjacent to double bonds and the origin of the relatively low barrier to rotation in *cis*-2-butene (*20*); tilted methyl groups; and such simple but fundamental chemical reactions as borane plus ammonia, reversible hydration of olefins, the ring- and olefin-producing reactions of the carbonium ion $CH_3CH_2CH_2^+$ (*29*), and carbene insertion reactions.

The Hellmann-Feynman Theorem

A consideration of the electrostatic forces on atomic nuclei in molecules adds another dimension to the uses of the tangent-sphere models.

All forces on atomic nuclei in molecules can be considered as purely classical electrostatic attractions and repulsions involving Coulomb's law. The force on a nucleus, according to the Hellmann-Feynman theorem (*7*), is simply the electrostatic force that would be exerted on this nucleus by the other nuclei in the molecule and by the molecule's electron cloud considered as a classical charge cloud that is prevented from collapsing by obeying Schrödinger's equation (*7a*).[5]

To use the Hellmann-Feynman theorem it is not necessary to have a detailed knowledge of the wave function. A knowledge of the ordinary 3-space electron density function is sufficient. Today, of course, even this is not known with any great precision for most molecules of chemical interest. One might well question, therefore, the use in a qualitative sense (see below) of a theorem that, strictly speaking, applies rigorously only to a mathematically exact electron density function—which we do not have. The answer must be that our procedure is not the procedure of applied mathematics but the procedure of a growing science. Qualitative applications of the Hellmann-Feynman theorem, such as will be described below, do seem to fall into a consistent, and therefore in some senses, useful pattern. This fact established, one might hope thereby to be able in the future to progress further, step by step, toward a satisfying description of molecular structure.

Effect of Lone Pairs on Bond Angles

The angle between single bonds that meet at an atom with unshared electrons is generally less than tetrahedral, 107° in ammonia, for example, and 104.5° in water. This fact has been described by saying that lone pairs behave as *s*-seeking centers (*30*, *31*). Such behavior can be rationalized as follows.

The carbon nucleus in methane experiences no net electrostatic force upon it—due to repulsions of the protons and to attractions of the bonding pairs—when it is in the center of its tetrahedral hole. (Calculations (*16a*) suggest that nuclei of first-row elements can be assumed to be at the centers of their $1s^2$ shells, which in the present context may therefore be regarded as part of the nucleus.) In ammonia, however, the center of the tetrahedral hole—for simplicity we suppose here that all valence-shell spheres are the same size—is not a position of electrostatic equilibrium for the nitrogen nucleus. To reach such a position the nitrogen nucleus must move away from the protons toward the lone pair. In effect the nitrogen atom nucleus is pushed toward the lone pair by the hydrogen atom nuclei. This diminishes the H—N—H angle and requires that less *p* character and more *s* character be included in the description of the lone pair orbital if this orbital is to be described in terms of spherical harmonics centered at the nitrogen nucleus.[6]

Effect of Electronegative Groups on Bond Angles and Bond Lengths

Both bond angles and bond lengths are affected by electronegative groups. In compounds of the type A—B—C the length of bond A—B often decreases as the electronegativity of substituent C increases (*32*);

Figure 35. Summary of the displacement of the electron cloud about an atom relative to the atom's nucleus (the small sphere) when the electronegativity of the substituents bound by the two downward-pointing valencies increases. The central atom's *p* character in these two valencies increases and, correspondingly, its *p* character in the two upward-directed valencies decreases. In drawing this figure the assumption has been made that the radial function associated with a *p* orbital is not as contracted as that of an *s* orbital.

similarly, in compounds of the type AB_2 and AB_3 the valence angle BAB frequently decreases as the electronegativity of substituent B increases (*33*). These effects have been summarized in a rule that states that the *p* character of an atom tends to concentrate in orbitals that the atom uses in bonds toward electronegative groups (*30*, *31*). This rule is illustrated diagrammatically in Figure 35.

Figure 35 might represent, for example, the change in the electron cloud about an oxygen atom that occurs in going from OH_2 (bond angle 104.5°) to OF_2 (bond angle 103.8°). In this case the small sphere in the cube center represents the oxygen atom core, the two lower spheres represent bonding pairs of electrons (in either O—H or O—F bonds), and the two upper spheres represent the unshared pairs on the oxygen atom. In going from OH_2 to OF_2 the bonding pairs move away from the

[5] In the context of the tangent-sphere models, it may be noted that minimizing the energy of a molecule with respect to the nuclear positions holding constant the positions and radii of the tangent-spheres yields the Hellmann-Feynman theorem. Minimizing the energy with respect to the sphere radii holding constant the nuclear positions yields the virial theorem.

[6] Dr. Kimball has remarked that "In discussing bond angles [to such elements as carbon, nitrogen, and oxygen] it is an important fact that the core (including the 1s pair) is small enough to move within the 'hole' at the center of the tetrahedron without overlap. The motion of the core within the hole is the principal, but not the only motion, affecting the bond angle. The less important motions are displacements of the protons within their spheres, and changes in the radius of the valence electron spheres."

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

oxygen nucleus and the angle subtended by them at the oxygen nucleus decreases; correspondingly the unshared pairs move in toward the oxygen nucleus and the angle subtended by them at the oxygen nucleus increases. The four arrows summarize the displacement of the electron cloud relative to the oxygen nucleus. The dotted lines indicate the new interorbital angles. If the wave function of a molecule can be satisfactorily expressed in terms of spherical harmonics centered at the nuclei, one may say that the change from OH_2 to OF_2 corresponds to shifting oxygen p character from the orbitals occupied by the lone pairs on oxygen to the bonding orbitals of the oxygen atom.

To this point, as well as in all other discussions of molecular structure based upon the use of atomic orbitals, the frame of reference adopted has been that of an observer standing at the location of an atomic nucleus and looking at the electron cloud about him from this fixed point. The tangent sphere model suggests a second frame of reference: the electron cloud itself.

From the point of view of an observer anchored to the electron cloud, the change in the position of the oxygen nucleus relative to the electron cloud when going from OH_2 to OF_2 can be represented in Figure 35 by a single arrow: one on the oxygen nucleus pointing upward.

A displacement of this kind seems reasonable. Electronegative atoms are atoms with large effective nuclear charges. These relatively unscreened charges exert on adjacent nuclei strong forces of repulsion that tend to drive the nuclei away from the electronegative atoms. Displacements resulting from these forces alter bond angles and bond lengths in a manner that is consistent in every respect with the previously cited rule regarding the distribution of atomic p character in molecules. Bond angles involving electronegative groups and bond lengths to substituents opposite electronegative groups will both tend to be smaller than normal, as is often observed.

Shapes of SF_4 and ClF_3

The sulfur-fluorine bonds in SF_4 are slightly shorter than the sum of the conventional covalent radii for sulfur and fluorine. It therefore seems reasonable to suppose that the sulfur-fluorine bonds in this molecule are conventional electron-pair bonds. This implies that the sulfur atom in SF_4 has an electron-pair coordination number of five (four pairs in bonds to fluorine and one pair unshared). The structure of this molecule has been determined recently by Tolles and Gwinn (*34*). Their results are given in Figure 36. The molecule can be considered to be a trigonal bipyramid in which one of the equatorial positions is occupied by a lone pair. The structure of this molecule appears to be consistent with the expectations of the tangent-sphere model.

Location of the lone pair at an equatorial position is reasonable since this places the "s-seeking pair" (*30, 31*) as close as possible to the sulfur nucleus.

The bonds to the axial fluorines (F_a) are slightly longer than those to the equatorial fluorines (F_e). This, too, is to be expected if the plausible assumption is made that the sulfur nucleus lies in the plane defined by the centers of the spheres that represent the equatorial electron pairs.[7]

That the actual ratio of bond lengths $(S—F)_{axial}/(S—F_{equatorial})$ is less than the calculated value is to be expected, also; for unlike the axial fluorine nuclei, which exert practically no net force on the sulfur nucleus, the equatorial fluorine nuclei exert a large resultant force on the sulfur nucleus in the direction of the lone pair. A displacement of the sulfur nucleus toward the lone pair would increase the axial-fluorine-sulfur distance less rapidly than the equatorial-fluorine-sulfur distance and would therefore diminish the value of the ratio of the first distance to the second. Such a displacement would also make the angle F_eSF_e less than 120°, as observed, and would cause the angle F_aSF_a to depart from 180° in the observed direction. Similar considerations apply to the molecule ClF_3, Figure 37.

Figure 36. Structure of sulfur tetrafluoride (*34*).

Figure 37. Structure of chlorine trifluoride.

Effect of Multiple Bonds on Bond Angles and Bond Lengths

The angle between two single bonds that meet at an atom bound by a double bond to another atom is generally greater than tetrahedral—118° for the adjacent C—H bonds in $H_2C=CH_2$, for example. Also, the length of the single bond from a substituent R to an atom X as a rule decreases as the remaining three bonds to atom X change from being all single bonds $(R—X\!\!<\!\!\!>)$ to one single bond and the components of a

[7] This analysis can be carried a step further. Insofar as the equal-sphere-size approximation for the valence-shell electron pairs of an atom is useful, one would expect the axial and equatorial bond lengths in SF_4, a molecule in which the central atom has an electron pair coordination number (EPCN) 5, to be, respectively, greater than and less than the S-F bond length in SF_6 (EPCN 6). The latter length is listed as 1.56–1.58 ± 0.02 Å. Thus, as expected,

$$(S - F_{axial})\text{EPCN } 5 > (S - F)\text{EPCN}6 > (S - F_{eq})\text{EPCN } 5$$

The difference between the first two is about 0.07 A. Similarly, the Xe-F bonds in linear XeF_2 (an EPCN 5 configuration that places the three unshared pairs in xenon's valence shell as close as possible to the xenon core—at the slight expense of the bonding pairs) are longer than the Xe-F bonds in XeF_4 (EPCN 6), again by about 0.07 Å. The experimental values recently reported for these Xe-F bond lengths are 2.00 Å in XeF_2 (Levy, H. A. and Agron, P. A. *J. Am. Chem. Soc.*, 85, 241 (1963)) and 1.93 Å in XeF_4 (Templeton, D. H., Zalkin, A., Forrester, J. D. and Williamson, S. M., *J. Am. Chem. Soc.*, 85, 242 (1963)).

double bond (R—X<—) to the three components of a triple bond (R—X≡). The C—H bond lengths in ethane, ethylene, and acetylene, for example, are 1.114, 1.086, and 1.055 Å, respectively. These facts can be reconciled with each other in the following fashion.

The carbon-carbon internuclear distance decreases from 1.53 to 1.34 to 1.20 Å in going from ethane to ethylene to acetylene. Correspondingly the coulombic force of repulsion between the two carbon nuclei increases. In the molecules just cited this mutual repulsion tends to drive the carbon nuclei into their respective C—H bonds. This outward thrust tends to make the valence angle opposite a double bond greater than normal, Figure 38. At the same time it tends to

Figure 38. Tangent-sphere model of ethylene. Small dots represent protons, larger dots carbon nuclei (small enclosing dashed circles represent 1s electrons). The carbon nuclei push each other toward the adjacent C—H bonds, with the results indicated. Straight lines illustrate the isomorphism that exists between a molecule's tangent-sphere model and valence-bond diagram.

Figure 39. Tangent-sphere model of acetylene showing the effect of the outward displacement of the carbon nuclei on several properties of the carbon-hydrogen bond (cf. Fig. 38).

make the corresponding C—H distance less than normal, the more so the closer the two carbon nuclei are to each other, Figures 38 and 39. Also, as the carbon-carbon internuclear distance decreases and the buttressing effect of one carbon nucleus on the other increases, the external C—H bonds are brought ever more under the influence of the carbon nuclei and the apparent electron-withdrawing power or inductive constant, σ, of the carbon atoms in these valencies increases (*35*) as does also the carbon(13)-proton coupling constant, J_{CH}, whose magnitude critically depends on the interaction between the electrons of the C—H bond and the carbon nucleus (*36*).[8]

This discussion also illustrates the appropriateness of a long-standing supposition (*37*); namely, that when describing the electron distribution in molecules in terms of spherical harmonics centered at atomic nuclei, it is proper to suppose that the radial function associated with an s-orbital is more contracted than that of the corresponding *p*-orbitals.

[8] The carbon-carbon spin-coupling constants reported recently by K. Frei and H. Bernstein (*J. Chem. Phys.*, **38**, 1216 (1963)) provide another illustration of the manner in which the properties of single bonds are influenced by the outward thrust of adjacent, multiply bonded carbon nuclei.

Mechanism of the Inductive Effect

The effect of electronegative substituents and multiple bonds on molecular structure can be summarized as follows. The location of atomic cores within their tetrahedral holes can be altered in two ways: by changing the nuclear charges on adjacent atoms (see section on "Effect of Electronegative Groups on Bond Angles and Lengths") or by changing the distances to adjacent atoms (see section on "Multiple Bonds). Taken together these two items provide a concrete picture of the inductive effect. Consider, for example, the molecular fragment R—C_1—C_2—C_3. As the electronegativity of substituent R increases, carbon-core C_1 is pushed toward carbon-core C_2; and as the distance between carbon-core C_1 and carbon-core C_2 decreases, carbon-core C_2 is pushed toward carbon-core C_3; etc. This description of the inductive effect is analogous in every detail to one given earlier by the author in which use was made of the rule concerning the distribution of atomic *p* character in molecules (*38*).

The Variable Effect of Multiple Bonds on Bond Lengths

The previous discussion provides an explanation for the curious fact that the change from a single bond to a double bond or from a double bond to a triple bond alters the length of an adjacent carbon-substituent bond relatively little when the substituent is hydrogen, somewhat more when the substituent is a methyl group, and still more when the substituent is chlorine (*31*, *39*). For as the carbon nucleus moves toward the substituent, the substituent will tend to ride further along the bond—corresponding to the picture of the inductive effect just cited—the larger the force constant of the carbon-substituent bond. One expects to find, therefore, an inverse correlation between the stretching force constant of a bond, which measures the resistance of the bond to changes in length, and the susceptibility of the bond to changes in length with a change in adjacent unsaturation. The larger the stretching force constant, the smaller should be the change in bond length. Typical stretching force constants for C—H, C—CH_3, and C—Cl bonds, are, respectively, 5.0, 4.5, and 3.4 millidynes/angstrom.

Conclusion

With the passage of time it seems likely that the discussion given above will prove to have only touched the surface of the possible applications of the tangent-sphere models.

Already it has been shown (*16a*, *b*) that with some simplifying assumptions regarding the nature of the charge distribution within each sphere—e.g., that it is uniform—it is possible to introduce Planck's constant into the treatment of complex molecules with a simplicity that exceeds and with an accuracy that rivals that of conventional, more complex treatments. Largely this is because the tangent-sphere treatment avoids the use of overlapping one-electron orbitals (*16*, Part I) and, hence, the very great and perhaps entirely artificial mathematical problems associated with exchange integrals (*9*, Part I).

On the other hand, the tangent-sphere treatment does partake of that part of current molecular orbital theory that is generally conceded to be sound: namely,

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

the requirement that the electron cloud be considered not as parts in isolation but as a whole. This happens quite automatically since the spheres by supposition are tangent to one another. Remove one of them and the shape of the set that remains, or the location of the atomic nuclei within the set, will generally change. The implications of this statement appear to be consistent with what is known about the shapes of radicals and of molecules in excited states.

Another feature of the model not discussed above concerns the role of charge correlation between electrons of two different spin sets. Probably always to a small extent and, following Linnett (*14*), perhaps sometimes to a large extent the centers of the Fermi holes of two spin-paired electrons will not be coincident. Some chemical implications of this extension of the model have been explored elsewhere (*40, 41*).

The qualitative features of the energetics of the model have been summarized by Strong (*19*): An assembly of atoms will be most stable when the electrons can be as large as possible, consistent with keeping electrons away from each other but close to the nuclei, while keeping the nuclei away from each other.

HF_2^-

F·····H·····F

Figure 40. Tangent-sphere model of the symmetrical hydrogen bond in HF_2^-. Large dots represent the fluorine cores. The small dot represents the proton.

Hydrogen bond formation (Fig. 40) has been described by Kimball (*18*). As the nuclear charge on the heavy atom increases in the sequence CH_4, NH_3, H_2O, HF, the protons are pushed closer to the surface of the shrinking electron pairs. Conversely, as the central nuclear charge decreases in the sequence NH_4^+, CH_4, BH_4^-, the protons approach the centers of their expanding electron pairs; these protonated pairs therefore become more hydridic and in the presence of sufficiently strong Lewis acids, such as Al^{3+} and BH_3, may be accepted, proton and all, into the valence shell of another atom, forming thereby, as in aluminum borohydride and diborane, protonated, three-centered bonds.

Many interesting problems, however, remain to be considered. Aromatic systems, for example, have been carefully ignored in the present discussion. Also, while one may agree that the models do work in some cases, it should be emphasized that it is not really known why they work as well as they seem to. In short, what has been described here is a model, not a chemical theory. Properly the models should be viewed as a supplement to, not a substitute for, quantum mechanics in an area where the latter has encountered severe computational problems. Perhaps some young reader of THIS JOURNAL may someday see how to achieve a happy union between these models of the experimental facts of structural chemistry and the underlying principles of theoretical chemistry.

The cover

For an explanation of the model being held by Herbert Kirst, a sophomore chemistry major at the University of Minnesota, the reader is referred to stage 1 of Figure 33. The hydroxide ion on the reader's left and the components of methyl chloride on the reader's right can be moved along the horizontal dowel rod, which represents, in a sense, the reaction coordinate of the Walden inversion shown on the blackboard. The dowel rod passes through the center of the lone pair on the hydroxide ion that is attacking the CH_3—Cl bond and through the center of the sphere that represents the carbon-chlorine bond, or one lone pair of the displaced chloride ion. The dowel also passes through a hole in the center of a small triangular piece of wood that is glued into the trigonal hole of the methyl group, which is not glued or pegged to the C—Cl bond; in this way, the methyl group is kept properly oriented about the reaction coordinate.

TLC—Versatile Tool

Chromatography using thin layers of adsorbents on glass plates (thin layer chromatography, TLC) has been the subject of a number of current reviews (*1–6*). This technique has gained wide recognition as a simple and rapid method for the fractionation, analysis, and isolation of a great variety of substances. Complex mixtures of amino acids, lipids, vitamins, dyes, drugs, and inorganic anions and cations—to give a few examples—may be separated by this method, and remarkable results are often obtained. This versatile technique, which is currently being used in industrial and research laboratories throughout the world, often supersedes in usefulness other important methods of chromatography.

The simplicity and speed of TLC, and the low cost of the necessary equipment, make it an ideal tool for teaching through classroom demonstrations and laboratory experiments. Furthermore, TLC—unlike more laborious and time-consuming methods of chromatography, such as column chromatography—may be used by students after a few minutes of instruction.

Apparatus and Techniques

Applicators and Other Equipment. Most separations using TLC are accomplished in less than one hour, and simple and inexpensive methods for preparing thin layer plates have been described by Wollish (*6*) and others. Bekersky (*7*), for example, obtained them by spraying a suspension of adsorbent on glass (8- × 8-in.) with an ordinary spray bottle. Peifer (*8*) reported a method for coating lantern slides, microscope slides, and even microscope cover slips with thin layers of adsorbents. Recently, several uses of microscope slides for the separation of complex mixtures have been described (*9,10*). These inexpensive methods for preparing thin layer plates do not give the highly uniform layers that may be obtained with the Stahl or other commercially available applicators (*3*), but they are perfectly adequate for most applications of TLC where the mixtures to be resolved are not highly complex.

Chromatography tanks may be obtained from commercial sources at nominal cost or may be made from ordinary laboratory equipment. A glass beaker, for example, covered with aluminum foil or a glass plate, serves as a readily available and inexpensive chromatojar. Furthermore, capillaries made from narrow gauge glass tubing may be used instead of commercially available pipets when the application of exact amounts is not required.

Coating Materials, Solvents, and Indicators. Almost any coating material used in column chromatography, with or without added binder, such as calcium sulfate, may be used for the preparation of thin layer plates. Silica gel, aluminum oxide, cellulose, carbon, and mixtures thereof have the widest application.

The most widely used solvents for TLC are petroleum hydrocarbons, diethyl ether, benzene, chloroform, methanol, water, and mixtures thereof.

Most indicators that have found application to paper chromatography are suitable for TLC. The following indicators are used extensively: water (for compounds that are immiscible with this solvent); iodine vapors; 2′7′-dichlorofluorescein in 95% ethanol-ultraviolet light; and sulfuric acid (50%) with charring. These indicators may be used individually or consecutively on the same plate.

Chromatographic Procedure. TLC is usually conducted as follows: the sample, dissolved in solvent, is applied about $^3/_4$ in. from the edge of the plate with a micropipet or capillary. The plate is then placed in a chromatography tank containing solvent. Rapid equilibration is obtained if one or two sides of the tank are lined with filter paper that extends into the solvent. After the solvent has reached a height of about 5 in., the plate is removed and the resolved components are usually revealed by a spray indicator.

Lecture Demonstrations

TLC, because of its speed and simplicity, makes a highly effective lecture demonstration. The thin layer chromatogram shown in Figure 1, for example, illustrates the separation of a mixture of dyes (100 mg; principally 4-dimethylamino-azobenzene, Sudan Red G, and indophenol) on silica gel. In this experiment, a series of spots was placed across one edge of the plate so that sufficient amounts of each separated component could be isolated in pure form. The chromatogram was developed by elution with 90:10 v/v of petroleum hydrocarbons (bp 30–60°)–ethyl acetate, which effected partial separation of the mixture after only 5 min.

Figure 1. Preparative TLC, separation of a mixture of dyes: adsorbent, Silica Gel G; solvent, petroleum hydrocarbons (bp 30–60°)–ethyl acetate, 90:10 v/v; amount, 100 mg. From bottom to top: Sudan red G, 4-dimethylamino-azobenzene (blue), and indophenol (yellow).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

In one hour, the different colored bands were completely separated as shown in the figure. The dyes were then scraped off the plate with a razor blade and eluted from the adsorbent with chloroform. Each dye was obtained in pure form after evaporation of the solvent. This experiment, which provides a colorful demonstration of chromatographic methods of separation and recovery, was recently performed without difficulty by a first-year junior high school student.

Laboratory Experiments

TLC has proven to be highly successful for the separation of classes of compounds that migrate at different rates by virtue of their respective polarities, i.e., according to type and number of functional groups. As an example, the different migration rates of a variety of fatty acid derivatives, ranging in polarity from hydrocarbons to phospholipids, are illustrated in Figure. 2. Although subfractionations are sometimes perceptible, they do not usually interfere with separations according to class (*11*). It is noteworthy that the adsorption sequence of these aliphatic derivatives is comparable to that established by Brockmann (*12*) for aromatic compounds containing similar functional groups.

Figure 2. TLC of lipid classes: adsorbent, Silica Gel G; solvent, petroleum hydrocarbons (bp 30–60°)–diethyl ether–acetic acid, 90 : 10 : 1, v/v/v; indicator, 2', 7'-dichlorofluorescein, 0.2% in ethanol; amounts: 20γ, each. The letters correspond to compounds as follows: (a) 9-octadecene, (b) oleyl alcohol, (c) oleylaldehyde, (d) oleic acid, (e) methyl oleate, (f) cholesteryl oleate, (g) monoölein, (h) diolein, (i) triolein, (j) trilinolein, (k) trilinolenin, (l) tributyrin (α) plus tristearin (β), (m) cholesterol (n) selachyl alcohol, (o) chimyldiolein, (p) oleyl oleate, (q) dioleoyl lecithin—From Malins and Mangold (*11*).

The following simple experiment is recommended for use in high school and junior high school classes in science: a mixture of equal parts of castor oil, olive oil, and petroleum jelly is dissolved in diethyl ether and chromatographed together with standards on silica gel (Fig. 3). The components are revealed by spraying the chromatogram with 0.2% 2′,7′-dichlorofluorescein in ethanol (*13*). If, in addition, the plate is placed under an ultraviolet light, the spots will exhibit a vivid fluorescence. The chromatogram should be viewed for only a few moments through glasses to protect the eyes. The spots are also revealed by spraying the chromatogram with 50% sulfuric acid followed by *gently* heating the plate until charring occurs (*3*). Experiments may also be conducted on readily obtainable mixtures such as various naturally occurring oils (*13*), vegetable pigments (*9,14*), vitamin formulations (*3*), and ink pigments (*15*).

Organic Syntheses. In organic synthesis classes, the student is not only obliged to obtain a product but also to isolate it in relatively pure form and to determine its physical and chemical constants. If his reaction has not gone well, or if his yield is poor, he may not be aware of his predicament until he has spent several hours isolating and characterizing the product.

TLC can help solve these problems. This technique has been used for following the course of chemical reactions. Over prescribed intervals of time, for example, small aliquots of a reaction mixture may be removed and chromatographed on thin layer plates—often without prior removal of the solvent. This rapid procedure does not require the use of laborious time-consuming chemical analyses and eliminates the necessity for isolating intermediates, side-products, and products in the analysis of the reaction mixture. An excellent example of the use of TLC for monitoring chemical reactions was recently described by Gauglitz and Lehman (*16*), who determined the rate of conversion of triglycerides to alkyl esters in an alcoholysis reaction. The disappearance of the triglycerides and the simultaneous formation of the alkyl esters was graphically demonstrated by TLC (Fig. 4).

TLC is also highly effective for the isolation of small quantities (usually 10 to 100 mg) of compounds from crude reaction products. The use of this technique for preparative purposes not only saves the student time but also gives him a valuable working knowledge of the fundamentals of chromatography as well. In addition, TLC is a simple and direct method for obtaining very pure derivatives for elemental analyses, melting points, optical rotations, or other chemical and physical determinations.

Organic Analyses. Mixtures of organic unknowns are usually fractionated by their relative solubilities in different solvents. Other methods, such as acid-base washings, may then be used to further purify the resolved components. The pure compounds are finally characterized by their physical and chemical constants, or by the melting points of their derivatives.

Substances analyzed by TLC may be identified by the use of selective spray indicators (most indicators used in paper chromatography are applicable to TLC) (*6*). Resolved compounds may also be removed from

Figure 3. TLC of (a) castor oil, (b) olive oil, (c) petroleum jelly, and (d) mixture of (a), (b), and (c). Adsorbent, silica gel G; solvent, petroleum hydrocarbons (bp 30–60°)–diethyl ether, 85:15, v/v; Amount, 500 γ each spot; Indicator, 50% sulfuric acid, charring.

the adsorbent and further analyzed by complementary methods. Sufficient amounts of compounds may usually be obtained by TLC for the determination of the usual physical (melting point and refractive index) and chemical constants (specific reactivity with various reagents) that are generally required to characterize a compound. TLC, therefore, may be used to great advantage in courses in organic analysis and may often serve to supplement, or even replace, traditional methods of separation, isolation, and identification.

Mixtures of low molecular weight volatile compounds may also be readily fractionated by TLC as their derivatives. Low molecular weight substances such as aldehydes, for example, have been fractionated as 2,4-dinitrophenylhydrazones (*17*) by this method, and so have mixtures of 2,4-dinitrophenyl derivatives of short-chain amines (*3*). These derivatives may be recovered from the adsorbent in 10–100 mg amounts as described previously, and their melting points may be determined without further purification. Using these techniques, the student would find that time-consuming crystallizations are unnecessary and that derivatives obtained in this way generally give sharp melting points and are free of contaminants.

General Applications

Several new applications of TLC have been reported recently. Reversed-phase partition TLC on siliconized silicic acid was found to be useful for the fractionation of compounds in homologous series. Fatty acids, for example, were fractionated by this method according to chain-lengths and degrees of unsaturation (*11*). Mercuric acetate adducts of long-chain unsaturated compounds were also readily separated according to degrees of unsaturation on silicic acid plates (*18*). Ionophoresis has been described by Honegger (*19*), who combined this innovation with two-dimensional TLC for the separation of amines and amino acids. Remarkable separations of complex mixtures of *cis*, *trans*, and positional isomers on thin-layers of silicic acid impregnated with silver nitrate have been reported by Barrett and co-workers (*20*). Most separations using TLC have been conducted on mixtures of organic compounds. This technique, however, has recently been used for the separation of inorganic compounds and also for the fractionation and identification of a variety of anions and cations (*21–25*).

One of the most rewarding applications of TLC is in analytical and preparative radiochemistry (*26–28*). Trace amounts of compounds have been detected and analyzed by using the isotopic derivative technique: i.e., the detection and analysis of components in mixtures after reaction of their functional groups with radioactively labeled reagents. TLC has also been applied to the determination of radiochemical purity of compounds prior to their use in metabolic studies. The isolation of highly pure radioactive compounds from crude synthetic preparations and complex biological mixtures has also been successfully undertaken by use of this method (*27*).

The use of the isotopic derivative technique in conjunction with TLC is demonstrated by the autoradiograph of ^{14}C-esters of castor oil fatty acids (Fig. 5) (*27*).

Figure 5. Autoradiograph of methyl-^{14}C-esters (A) and acetoxy-^{14}C-acids (B) from castor oil—from Mangold, Kammereck, and Malins (27).

In this experiment, a sample of the total fatty acids was esterified with radioactive diazomethane. Another sample was acetylated with radioactive acetic anhydride. The ratios of the different classes of acids were then evaluated by counting the respective activities of the ^{14}C-esters after their separation by TLC.

Because of its simplicity, speed, and versatility, TLC will become a highly valuable tool in the classroom and laboratory. About a thousand papers and three books (*29–31*) have been published on this method. Educational films on TLC have been prepared by Dr. O. S. Privett of the Hormel Institute, Austin, Minnesota, Dr. E. H. Ahrens, Jr., of the Rockefeller Institute, New York, and Dr. H. Seiler, Institut für Anorganische Chemie, Universität Basel, Basel, Switzerland.

TLC on Microscope Slides

An organic chemistry experiment

Thin layer chromatography (TLC), a micro method of adsorption chromatography, possesses distinct advantages over paper chromatography. Specifically, the separations are faster and the developed spots are sharper. With inorganic adsorbents it is possible to use detecting reagents which are destructive to paper, e.g., conc. sulfuric acid, basic permanganate, etc.[1] The following experiment illustrates the general utility of thin layer chromatography as a method of separation; all techniques commonly employed are introduced.

Figure 1. Applicator and applicator board.

The laboratory work consists of three short experiments: (1) Separation of three mixtures of dyes, the components of which are known, and an unknown dye mixture to identify; (2) Separation of a known mixture of seven phenols and an unknown phenol to identify; and (3) Separation of dyes and impurities present in each of three fluorescein dyes. It is advantageous to show at least one of the following films in the introduction of thin layer chromatography to a class:

"Thin Layer Chromatography" produced by E. H. Ahrens, Jr., Rockefeller Institute. Playing time: 10 minutes.

"Thin Layer Chromatography" produced by O. S. Privett, Hormel Institute. Playing time: 45 minutes. This film requires a Bell and Howell 302 Magnetic Sound Projector.

The essential pieces of equipment are an applicator and applicator board (see Fig. 1), a plastic ruling bar for channeling the plates, Peerless wooden applicator sticks[2] which are used as a substitute for micropipets, a 4 oz. developing jar[3] with a plastic cap, an all-glass spray bottle that delivers a fine mist, a short-wave ultraviolet light, and microscope slides. The applicator may be fashioned from a 3 in. length of 1 × 1-in. aluminum or plastic bar. The front edge is undercut 0.25 mm and machined uniformly. Plexiglas sheet, $^1/_4$-in. thick, is satisfactory for the construction of an applicator board.

All the chemicals were Eastman white label except as noted. The dyes and phenols are listed in the table. In the preparation of solutions methanol was used as the solvent. The known phenol solution[4] contained 3% of each of the seven different phenols; and the unknown solution, 1% of the phenol. All other solutions were 0.1% with respect to each dye, except rhodamine B, which was 0.05% and Sudan IV, which was 0.03%. It was necessary to dissolve Sudan IV in hot methanol.

The Experiment

Eleven slides were aligned on the applicator board.

Five ml of water and 2.5 g Brockmann silica gel G[5] were mixed thoroughly. This mixture was applied to the slides with the applicator. The coated slides were activated for 10 min at 105°. To mark the solvent front, a heavy line was drawn $^1/_2$ cm from the top of the plate; 6 cm below this line the starting points were marked lightly and spaced according to the number of spots to be developed on the slide. By channeling the coated slides, it was possible to separate four different mixtures on one slide.

Four ml of the developing solvent were placed in the jar. The composition of the solvent systems is listed in Table 1. To saturate the atmosphere in the container, the jar was capped and swirled vigorously for approximately 20 sec. The spotted plate was lowered carefully into the solvent and the jar capped. When the solvent reached the 6 cm mark, the plate was removed from the container and air-dried at least 10 min. The intrinsic color of the dyes makes the developed spots visible. After developing and air-drying, the phenol plate was sprayed lightly with 0.1% solution of 2′7′-dichlorofluorescein in methanol.[6] Under ultraviolet light the phenols appeared as purple spots on a lavender or fluorescent yellow background. The developed fluorescein dye plate was dried 10 min at 105° then viewed in direct light and under ultraviolet light. Heating the developed plate intensified the fluorescence of the spots. The distance traveled by each component was measured and the R_f value calculated.

The R_f values determined for the dyes, phenols, and fluoresceins are summarized in Table 1. A tracing of each separation is shown in Figure 2. The dichlorofluorescein and tetrabromofluorescein dyes each contain impurities which probably are unreacted fluorescein and the corresponding mono-, di-, tri-, or tetrahalogenated fluorescein.

Separations on these coated slides are characterized by the same degree of sharpness obtained with larger chromatoplates. Since the R_f values determined by thin layer chromatography are not entirely reproducible, it is essential to run a known mixture and an unknown on the same plate. Saturation of the atmosphere in the developing chamber, prior to developing the plate, reduces the developing time and improves the quality of the spots.

Figure 2. Tracing of developed chromatoplates *Dyes*, (*A*), known mixtures 1, 2, 3, and unknown—from bottom to top the colors are: blue, violet, yellow, and orange. The components of the unknown are: methylene blue, crystal violet, o-cresolsulphonephthalein, and Sudan yellow, *Phenols*, (*B*), known mixture and unknown-phloroglucinol. *Fluorescein dyes*, (*C*), (1) Fluorescein, (2) Dichlorofluorescein, (3) Tetrabromofluorescein (Eosin Y). The shaded spots are visible in direct light while the circles represent spots visible only under ultraviolet light.

In practice thin layer chromatography on coated microscope slides is a rapid method for following the course and, qualitatively, the rate of a number of organic reactions, e.g., esterification of an alcohol, ammonolysis of an ester, and nitration of aromatic compounds. This technique is especially useful in determining optimum conditions for separating compounds by column chromatography.[7,8] A solution of 0.1% 2′7′-dichlorofluorescein in methanol is a general reagent for detecting aromatic compounds.

TLC Separation of Ink Pigments

Separation of pigments of writing inks by the thin layer chromatographic techniques was used quite successfully as a student laboratory exercise and as a rapid lecture demonstration of this recently developed analytical separation method. The experiment is an adaptation of a paper chromatographic separation described in Reilly and Sawyer.[1] In our experiment, a thin layer of activated silica gel on a glass plate was used as the absorber, and ethanol was used as the solvent. The inks chosen for this demonstration were four of the Sheaffer's "Script" "washable" writing fluids, black, blue, green, and purple. In addition to the visible pigments, the manufacturer advertises the presence of "RC-35," a fluorescent ingredient which makes it possible to determine the original inscription in case of erasure.

The separation of inks into their component pigments was chosen for its simplicity in illustrating techniques and choice of solvents for thin layer chromatography; and, in addition, affords the student the opportunity to visually observe the course of the separation.

One ml of each ink was added to five ml of 95% ethanol. 5λ (0.005 ml.) of this solution was applied to the coated plate. If quantities as large as one drop are used, it is suggested that the ink be diluted further.

A series of glass plates, 1 in. × 8 in. were coated with silica gel by one of two methods. In the first method, a homemade applicator was used. This was an aluminum trough sliding on aluminum rails mounted to a flat slab. The aluminum rails were slightly thicker than the glass plates used and were spaced so that eight plates could be coated at one time. To 10 g of Kieselgel (Arthur H. Thomas, Philadelphia, Pa.) was added 23 ml of water, and the mixture stirred until thoroughly dispersed. This slurry was poured into the trough and the trough was drawn over the plates.

The second method of coating followed the procedure given by Bekersky[2] where the absorber was sprayed onto the plates. This resulted in plates of more uniform coating, and furthermore, allowed the students to study as laboratory exercise the effect of layer thickness on the degree of separation. To spray the silica gel slurry on the plates, either a Fisher atomizer (Fisher Scientific Co., New York) or a dentist's oral atomizer (L. D. Caulk Co., Newark, N. J., or any dental supply company) was attached to a small compressor or a nitrogen cylinder set at 10 psi. Best results were obtained when 10 g of Keiselgel were mixed with 30 ml of water. The plates were placed on a flat surface, and the atomizer held approximately 12–18 in. from the plate while coating. One slow pass with the sprayer provided a coating equal to the conventional applicator.

After the silica gel was applied, the plates were left in position for 10–15 min for the silica gel to set. The plates were then activated by drying in an oven at 110°C for 1 hr. Until use, the activated plates were stored in a desiccator over calcium sulfate.

Five lambda (0.005 ml) of the ink solution was applied to a plate 1.5 cm from the bottom, and a line was inscribed on the plate 10 cm above the uppermost edge of the spot. The plate was then placed in a 250 ml cylinder containing about 5–10 ml of 95% ethanol, and the cylinder was stoppered.

Solvent rise was quite rapid, and separation of the components of the ink was immediately noticeable. By shining an ultraviolet light on the plate, separation of the ultraviolet constituent could also be observed. When the solvent front had reached the 10 cm line, the plate was removed from the cylinder and air dried. The distance traveled by each component was measured and the values of R_f calculated. No attempt was made to determine the chemical composition of each constituent; however, by using the black ink, and a variety of solvents, the effect of changing solvent polarity on the degree of separation was investigated in the student laboratory. The table shows the results obtained for four colors of ink with 95% ethanol used as the solvent, for it appeared to give the best separation in the shortest time. In trying other solvent systems, it was found that the silica gel plates could tolerate up to 20% water in the solvent; beyond this, the thin layer would flake off the plate. Best separations were achieved by polar, water-like solvents, while non-polar solvents gave zero values for R_f.

R_f Values for Constituents of "Script" "Washable" Writing Fluids on Silica Gel Plates, Ethanol Solvent

Ink	Constituent	R_f	Comments
Black	"RC-35"	0.96	.....
	Yellow	0.94	Narrow band
	Red	0.92	.....
	Blue	0.80	Wide band
Blue	"RC-35"	0.93	.....
	Blue	0.92	Trace amount
	Dark Blue	0.85	Relatively narrow band
	Blue	0.00	Trace amount
Green	"RC-35"	0.95	.....
	Yellow	0.93	.....
	Blue	0.78	.....
Purple[a]	Blue	0.85	Very narrow band
	Red	0.84	Narrow band
	Purple	0.74	Wide band
	Dark blue	0.00	Trace amount

[a] Although the ink itself fluoresced under an ultraviolet light, no trace of an ultraviolet constituent could be found for this particular sample on the chromatographic plates.

Electrophoretic Study of Synthetic Food Dyes

At the present time the United States Government allows eleven synthetic dyes to be used in food products. Many papers dealing with the separation of these dyes and the study of their impurities have been published in the last decade. The majority of these works have examined paper chromatography as a technique of separating simple dye mixtures (*10, 13*) and of identifying colored impurities in individual dyes (*2, 3*). A few attempts have been made to separate simple dye mixtures by column chromatography using alumina as the adsorbent (*5, 7*). A characteristic of almost all of these papers is the multiplicity of solvent systems employed.

Some early work had been done to separate simple dye mixtures electrophoretically (*3, 6, 11, 12*). The use of paper, however, as a supporting medium in these experiments proved to be unsuccessful. In the paper by Šramek (*9*) the chromatographic behavior of disperse dyes is studied in relation to their molecular configuration. A study of the electrophoretic behavior of food dyes from this point of view afforded an excellent student project. Our work includes a study of the effect of charge density and mass of dye molecules on their mobility in an electric field.

The experiments were performed in a simple electrophoresis apparatus, using cellulose acetate membrane as the supporting medium. This membrane has previously been employed with success in the electrophoretic separation of proteins and amino acids (*1, 4, 8*).

We were able to separate the components of complex mixtures of food dyes with one buffer system. Depending upon the number of dyes involved and their chemical structure, a complete run took from a few minutes to less than 2 hr. Complete separation of as many as seven dyes was accomplished on a 5-in. strip in 1 hr.

The apparatus constructed for the experiment was a simple electrophoresis cell, consisting of two large (200 ml capacity) shallow Plexiglas containers and two similar containers half as large (Fig. 1). Notches were cut along the tops of the narrow sides of the large containers so that glass rods could be laid across them at varying distances. Across these parallel rods were stretched the cellulose acetate strips with steel clips at each end to prevent sagging. Into each smaller container was placed a carbon rod, electrically connected to a power supply consisting of three 90-v dry cell batteries. Each small container was, in turn, connected to one of the large ones by means of cotton wicks enclosed in glass tubing. The cover was dome-shaped in order to cause condensed droplets to move to the sides and prevent them from falling on the strip. The buffer solution used in the experiments consisted of equal parts of 0.1 *M* sodium acetate and isopropyl alcohol adjusted to *p*H 4.6 with acetic acid.

The experiment was conducted in the following manner: The containers were all filled to two-thirds of their capacity with the buffer solution. The cellulose acetate strip, cut to proper size, was thoroughly wetted with the buffer. Excess liquid was removed by pressing the strip between two pieces of absorbent paper. The dye mixture in solution was spotted approximately an inch from the midpoint of the strip with a capillary or a micropipet, and the weights were attached at each end. The current was then turned on, and the strip was laid across the properly spaced glass rods in such a manner that the dye mixture was closer to the cathode than to the anode. The cover was then put in place, and the experiment was timed.

Figure 1. Electrophoresis apparatus.

When a charged ion is subjected to an electric field, it migrates toward one of the electrodes. The velocity of this movement depends upon the magnitude of charge and structure of the ion and upon certain factors in its surroundings. These environmental factors include concentration and *p*H of the buffer solution, applied potential, chemical, and physical characteristics of the supporting medium, and temperature and viscosity of the buffer. If the environmental factors are strictly controlled, the rate at which an ion migrates depends only upon the properties of the ion itself.

All eleven of the food dyes approved by the United States Government are sodium salts which, in an aqueous solution, dissociate into the sodium ion and the dye anion. The latter carries a net negative charge. The magnitude of the charge depends on the number of dissociable sodium ions in the dye molecule.

It was found that, under applied potential, the velocity of migration is greater for dye acids which have a higher net charge. Also, among dyes which have the same charge, the speed of migration decreases as the molecular weight increases. Thus, if all eleven dyes are classified into groups of trisodium, disodium, and monosodium salts, and the members of each group are listed in the order of increasing molecular weight (Table 1), the resulting pattern conforms with the sequence of zones produced by the electrophoretic separation of the dyes (Fig. 2).

Table 1. Dyes Grouped According to Number of Dissociable Sodium Ions and Increasing Molecular Weight in Each Group

Official name	Classification	Dissociable sodium ions	Molecular weight
FD&C Yellow no. 5	Pyrazolone	3	534
FD&C Red no. 2	Monoazo	3	604
FD&C Yellow no. 6	Monoazo	2	452
FD&C Blue no. 2	Indigoid	2	466
FD&C Red no. 4	Monoazo	2	480
FD&C Green no. 2	Triphenylmethane	2	792
FD&C Blue no. 1	Triphenylmethane	2	792
FD&C Green no. 3	Triphenylmethane	2	808
FD&C Red no. 3	Xanthene	2	898
FD&C Green no. 1	Triphenylmethane	1	690
FD&C Violet no. 1	Triphenylmethane	1	733

Two of the dyes (Green 3 and Red 3) do not seem to fit this rule. Red 3 remains practically at the starting point. Green 3, although it has a greater molecular weight than Blue 1 or Green 2, moves ahead of these two dyes. We suspect that, even though Green 3 has a higher molecular weight than either of these two isomeric dyes, the presence of a hydroxyl group in its molecule could be the cause of this discrepancy. The immobility of Red 3 can be explained by the fact that, at the *p*H of our normally used buffer, this dye is so insoluble that it hardly moves from the point of applications. However, if the *p*H is raised above 6.0, this dye migrates ahead of the two monosodium dyes, Violet 1 and Green 2, and occupies its proper position on the membrane.

The dyes of the triphenylmethane group exhibit several noteworthy characteristics. They oxidize readily and are susceptible to fading when exposed to light. These problems may be minimized if the experiment is conducted in the dark under an inert atmosphere. This group also seems to possess the largest number of subsidiary dyes, some containing as many as four. We are currently investigating the problem of impurities in these dyes.

Paper was found to be an unsatisfactory supporting medium. It has a strong adsorptive power which causes tailing during separation. Cellulose acetate membrane, however, proved to be an excellent medium. It has uniform porosity and, due to the loss of most of its hydrophilic groups during processing, it has minimal adsorptive power. This eliminated tailing in our experiment.

Figure 2. Electrophoretic pattern of eleven food dyes on cellulose acetate membrane.

A Gas Chromatography Demonstration Apparatus

An inexpensive apparatus for the separation of volatile organic compounds by gas chromatography has been described,[1] in which hydrogen was used as the carrier gas. The gas was burned as it emerged from the apparatus and the detection of components was accomplished by studying visual changes in the nature and height of the flame. For the purpose of class demonstration of gas chromatography it is necessary to use hydrogen under a pressure of 2–3 lb/sq in. in order to get a flame which is long enough to be visible. This introduces a hazard as the serum cap may be blown off and the pressure hydrogen become ignited by the burning emergent gas. These dificulities with respect to flame height and fire hazard have been overcome by modifying the technique so that hydrogen is replaced by oxygen or air as carrier gas and the emergent gas is led into a coal gas flame which may have a height of 2 to 3 in.

Figure 1. Diagram of the apparatus.

A convenient mixture for demonstration purposes is one containing chlorinated hydrocarbons which can be detected readily by means of a copper wire suspended in the coal gas flame.

The apparatus consists essentially of a Pyrex U-tube (30 in. in length; 6.5 mm id; 8.5 mm od). The carrier gas and coal gas inlets are arranged as shown in Figure 1.

The U-tube was packed with Celite (80–120 mesh) which had previously been treated with silicone oil as partitioner. The coal gas was ignited at the emergent orifice to give a luminous flame 2- -3-in. high. Oxygen at a pressure of 3 lb/sq in. or air at a slightly higher pressure was then passed through the apparatus; and if the coal gas flame remained luminous, the coal gas supply was adjusted accordingly. The sample (0.02 ml) which consisted of a ternary mixture of ethyl chloride, methylene chloride, and chloroform in the volume ratio of 1:1:1, was introduced via the serum cap by means of a hypodermic syringe. When one of these components appeared in the emergent gas, it imparted a green color to the flame as a result of the volatility of the copper halide formed on the copper wire detector.

When the apparatus was operated at ambient temperature (approximately 14°C) ethyl chloride appeared in the emergent stream after 45 sec, the flame coloration reaching a maximum after an additional 12 sec and finally disappearing after a further 12 sec. Methylene chloride appeared after the lapse of 100 sec from the time of introduction of the sample and burned for a total period of 50 sec while chloroform appeared after 250 sec and burned for 50 sec.

Besides offering a safe and easily visible demonstration of the separation of organic liquids by gas chromatography, the apparatus lends itself to the drawing of curves in which time is plotted against the intensity of the flame luminosity. By conducting the experiment in a semidark room and by focusing the copper halide flame on a Weston Master III universal exposure meter by means of a lens, the graph shown in Figure 2 was obtained for the ternary mixture above using compressed air at a pressure of 6 lb/sq in. as carrier gas.

Figure 2. Intensity of flame luminosity versus time for a ternary mixture

Impressed by the success of the above separation we directed our attention to experiments of a semiquantitative nature. In these, the Celite column was

[1] Cowan, P. J., and Sugihara, J. M., J. Chem. Educ., 36, 246 (1959).

inserted in the air stream leading to the photometer as in Figure 3 and readings were taken on the galvanometer at 10 sec intervals. Using mixtures of chloroform and methylene chloride in varying proportions and a copper wire detector, the galvanometer deflections were plotted against time; and it was shown that the ratio of the areas under the curves is the same as the ratio of the total chlorine content in the individual components of the mixture—see Table 1.

Figure 3. Insertion of Celite column in air stream.

Table 1. Carrier Gas—Compressed Air at 7 lb/sq in.

Mixture	Molar ratio $CHCl_3$: CH_2Cl_2	Area ratio	Chlorine ratio
A	1:1	1.51	1.50
B	1:2	0.81	0.75
C	2:3	1.04	1.00
D	2:1	3.1	3.00

That the areas bore a direct relationship to the total amount of chlorine present in each component was to be expected as the copper wire detector system is in fact trapping chlorine only. In this connection it was observed that for mixture D, which contained the highest proportion of chloroform, it was necessary to replace the single strand of copper wire used as detector by a copper coil in order to obtain area results which showed good agreement with the chlorine ratio.

Subsequent experiments revealed that the combination of the gas chromatographic column with the flame photometer could be used for detecting a wide range of organic compounds embracing hydrocarbons, halogenated hydrocarbons, ethers, aldehydes, ketones, amines, and esters, without the use of a special copper detector for halogenated compounds. Provided the vapor which is being detected causes an alteration in the luminosity of the flame, the photometer will serve as an efficient detector; and the only compounds tested which could not be detected satisfactorily were methanol and ethanol.

Table 2. Time and Duration of Flames for Organic Compounds in Demonstration Apparatus

Compound	Appearance of flame (sec)	Duration of flame (sec)
Acetaldehyde	35	20
Ethyl chloride	40	20
Acetone	76	34
Diethyl ether	80	30
n-Pentane	80	20
Methyl iodide	85	30
Methylene chloride	98	38
Methyl acetate	100	50
Ethyl amine	150	40
Chloroform	190	55
n-Hexane	210	50
Benzene	295	105
Cyclohexane	340	100
Cyclohexene	385	120

Table 2 shows the results obtained with various classes of volatile organic compounds using compressed air at 7 lb/sq in. as carrier gas. The time taken for the vapor to appear is noted and also the time of duration of the flame so that from the data provided in Table 2, one can predict which mixtures of the compounds shown could be separated by the procedure described. For example, there would be no difficulty in separating the components of a mixture containing acetone and chloroform, or *n*-pentane and *n*-hexane, or *n*-hexane and benzene. It was also found, that under a standard set of conditions, viz., constant pressure of carrier gas and constant room temperature, the retention times for various compounds could be reproduced to within a few seconds representing a divergence of less than 5%. For higher boiling compounds, the U-tube may be immersed in a constant temperature oil bath, but this does not add to the teaching value of the apparatus.

U.S. HEW New Publications

The office of Education of the U.S. Department of Health, Education and Welfare has recently issued "Educational Media Research in the Far East" (0E 34025—$0.70). It includes a survey of the overall educational situation in the Far East and a country-by-country report on the progress of projects using new media, e.g., television.

Another recently released pamphlet is "Science Publications, An Annotated Guide to Selected Listings" (0E 29046—$0.40). It is, in effect, a list of published lists of books and reading materials suitable for school students and teachers. All areas of biological, physical, and earth sciences are covered.

Determining Activity Coefficients by Gas Chromatography

A physical chemistry experiment

Classical methods of determining activity coefficients of non-electrolytes are laborious (*1*) and not as accurate or precise as desirable (*2*). On the other hand, the use of gas-liquid chromatography affords a fast, simple method for making these measurements. A simple, gas-liquid chromatographic experiment which can be performed by students in undergraduate physical chemistry is outlined for the determination of the activity coefficients of benzene, cyclohexane, and cyclohexene in dinonylphthalate.

Since the column of the gas chromatograph can be considered the site of a dilute solution, a correlation exists between gas-liquid chromatographic data and the activity coefficient of a solute in solution. The necessary link is found in the specific retention volume, V_g, which by definition is the volume of carrier gas reduced to zero °C which is necessary to elute a given solute, per gram of liquid phase. This quantity is independent (to a first approximation) of any of the operational variables of the column; it is a function of the temperature alone. It measures the amount of time spent by the solute in the moving gas phase, which in turn is determined by how easily the solute can "escape" from the solvent into the moving phase. The "tendency to escape" is simply vapor pressure. Like other solution properties, it is altered by non-ideal behavior, and therefore activity coefficients are necessary in order to reconcile observed behavior with ideal behavior. Various investigators have successfully demonstrated this relationship between activity coefficients at infinite dilution and the gas chromatographic retention volume (*2–7*).

The simplicity of the gas chromatographic technique makes the measurement of activity coefficients by this method attractive for student instruction. The data which are obtained are accurate and can be used to explain some of the deviations from Raoult's Law; i.e., the nature of intermolecular forces in solution and the resultant deviations from ideality. Overall, this represents an ideal teaching situation.

Two very different instruments were used in this study; an F&M model 720 dual column gas chromatograph, and a home-made one. The latter was built around a Gow-Mac model 9285, 4-filament thermal conductivity cell[2] and used a Sargent Model SR recorder for readout. Using the same home-made column in both instruments, good results were obtained.

Column temperature was maintained between 40 and 60°C and had to be accurately measured. This was accomplished with either an accurate thermometer or a thermistor incorporated into a wheatstone-bridge type circuit. The injection port (and in the case of the F&M instrument, the detector as well) was kept at about 150°C. Helium was used as the carrier gas; flow rate was about 60 ml/min and was measured on the exit side of the carrier-gas line with a soap-bubble flow meter. A student-made manometer, placed in the carrier-gas line on the inlet side served to measure the inlet pressure. Samples were kept as small as practical (about 0.5 μl) and were injected with a 10 μl syringe.

Column. It is necessary that the liquid phase be pure, and that the exact amount of liquid phase in the column be known. Dinonylphthalate (molecular weight = 418.6) was obtained from Analytical Engineering Laboratories, Inc. and was used without further purification. The column packing contained 25.0% dinonylphthalate on 80 to 100 mesh Chromosorb. For the 3 ft of $^1/_4$-in. copper tubing used, this required a mixture of 2.50 g dinonylphthalate and 7.50 g oven-dried Chromosorb.

The efficiency of this column was found to be 525 theoretical plates. Such a column, if used below 125°C should be good for a minimum of 100 hr. A new column should be preconditioned for about 4 hr at 80°C before use.

The Experiment

The instrumental conditions prescribed earlier should be set at least 1 hr before any runs are made, in order to allow the column to come to equilibrium. With the recorder running, a 0.5 μl sample (including some air) is injected. The instrument sensitivity is adjusted so that the peak which is obtained is at least 20% of full scale. Samples of benzene, cyclohexane, and cyclohexene are run.

The following measurements are required:

Flow rate, F; av. of values taken before and after the run: in ml/min.
Adjusted retention time, t_R'; measured from the air peak; in cm.
Column temperature, T_c; in °K.
Room temperature, T_a; in °K.
Atmospheric pressure (outlet pressure), P_0; in cm Hg.
Column pressure (manometer reading), P_x; in cm Hg.

Total inlet pressure, $P_i = P_0 + P_x$.

Calculation.[3] The specific retention volume, V_g (in ml/g), can be calculated from equation (1):

[1] Abstracted in part from an honors thesis submitted by Susan Kenworthy to the faculty of Drew University, 1963.
[2] This cell is part of a kit from which the gas chromatograph was built.
[3] A sample calculation is available to instructors upon request to Dr. Miller.

$$V_g = \frac{P_0 - P_w}{P_0} \times \frac{273}{T_a} \times F \times \frac{t_R'}{2.54} \times \frac{1}{W_L} \times j \qquad (1)$$

where W_L = 2.50, the weight of the liquid phase in grams, P_w is the vapor pressure of water at room temperature, (T_a); and j is pressure gradient correction factor and equal to

$$\frac{3}{2}\left[\frac{(P_i/P_0)^2 - 1}{(P_i/P_0)^3 - 1}\right]$$

The factor, $t_R'/2.54$, is used because the recorder speed was 1 in./min and t_R' was measured in centimeters. If a different recorder speed is used, a new term will be needed in equation (1). The units on this term (taking into account the recorder speed) should be minutes.

Activity coefficient,[4] γ°, is related to specific retention volume by equation (2) (*8*):

$$\gamma^\circ = \frac{17.05 \times 10^6}{V_g \times f^\circ \times M} \qquad (2)$$

where M = the molecular weight of the liquid phase, and f° = the fugacity of the pure solute vapor in millimeters of mercury. To a first approximation, vapor pressure of the pure solute, p°, at the column temperature, can be substituted for fugacity, and can be calculated from data found in several reference works (*9*). Typical results are shown in the table.

Discussion

Benzene, cyclohexane, and cyclohexene were chosen for this experiment because comparable activity coefficients were already in the literature and showed a wide range of values. The close agreement between literature values and student values is shown in the table and indicates the reliability of this simple method.

A low activity coefficient ($\gamma^\circ < 1$) means that the partial pressure of the solute above solution is less than would be expected if Raoult's law were valid ($p = xp^\circ$). This implies that the solute molecule is being "held" in solution by some intermolecular force, hence reducing its "escaping tendency." We note that the escaping tendency of cyclohexane (γ° = 0.82) is greater than that of cyclohexene (γ° = 0.64) which, in turn, is greater than that of benzene (γ° = 0.52). Such negative deviations from Raoult's law can usually be attributed to one or both of the following causes: inequalities in the volumes of the molecules and disparities in their respective intermolecular forces.

[4] The superscript denotes "at infinite dilution." While this notation is preferable from a theoretical point of view, it must be admitted that this ideal is not attained in a gas chromatographic column, see (*11*).

In gas chromatography, the first cause is often important because the solvent molecule is usually much larger in size than the solute. In this study, however, this effect can be of only minor significance since the three solutes studied are nearly equal in size. Hence, the large differences in activity coefficients must be attributed largely to the second reason.

Dinonylphthalate is a moderately polar substance, and therefore it should be capable of polarizing the delocalized π-electrons of a solute molecule. For the three compounds being studied, the extent of polarizability, and hence the activity coefficient, depends upon the *number* of π-electrons. Since benzene has the largest number of π-electrons, the dispersion and induction forces present in its solution should be the highest, causing its activity coefficient to be the lowest. Cyclohexane, on the other hand, has no π-electrons and can be polarized only slightly. Its interactions with dinonylphthalate will be the smallest and its activity coefficient the largest. Cyclohexene has one double bond (2 π-electrons) and its activity coefficient lies in between benzene and cyclohexane as would be expected.

In addition, the previous considerations enable one to judge the selectivity of dinonylphthalate as a stationary liquid phase and to predict its utility for gas chromatographic separations. The relative volatility of two solutes x and y, (or the "separating power" of a substrate), $\alpha_{x,y}$, is given in equation (3) (*10*):

$$\alpha_{x,y} = \frac{(\gamma^\circ p^\circ)_x}{(\gamma^\circ p^\circ)_y} \qquad (3)$$

If α = 1, the substrate is completely unselective for x and y.

When α is evaluated for benzene and cyclohexane (x and y) in dinonylphthalate, one finds that the ratio of their vapor pressures is almost unity (see the table), so that α can be reduced to:

$$\alpha = \frac{\gamma^\circ \text{ cyclohexane}}{\gamma^\circ \text{ benzene}} = \frac{0.82}{0.52} = 1.6 \qquad (4)$$

Hence, it can be concluded that in this example, the separation was made on the basis of relative activity coefficients.

In gas chromatography, the prediction of activity coefficients and relative volatilities would be helpful in the selection of a liquid phase for a given separation. A theoretical approach to this problem has been taken (*11*), and the results of such studies should eliminate the need for extensive trial-and-error in the selection of a liquid phase for a given separation.

It is hoped that this experiment will stimulate the reader to try some similar experiments of his own: The effect of changing the inlet pressure or the sample

Typical Results.

Compound	F (ml/min)	t_R' (cm)	T_c (°K)	P_0 (cm)	P_i (cm)	p° (mm)	V_g (ml/g)	γ°	Av. γ°	Literature values Ref. (*2*)	Ref. (*7*)
Benzene	52.2	47.4	326	75.8	125.5	303.7	256	0.523	...	...	...
	51.3	50.9	325	75.2	123.3	292.6	270	0.515	...	...	...
	48.0	52.0	326	75.8	122.2	303.7	262	0.511	0.52	0.526	0.524
Cyclohexene	51.7	42.1	326	75.2	123.9	280.2	226	0.644	0.64	...	0.682
Cyclohexane	49.2	31.3	326	75.8	123.7	303.5	160	0.838	...	...	...
	52.6	31.0	326	75.2	124.4	303.5	168	0.796	0.82	0.842	0.849

The experimental data in this table were selected from a larger table of data because they were determined at a T_c of about 326°K. This was done in order to permit a comparison with the literature values which were also determined at this temperature.

A Diels-Alder Student Preparation

We find that a Diels-Alder reaction between tetracyanoethylene (Columbia Organic Chemicals Co., Inc.) and anthracene (Eastman practical) serves very well for a simple, rapid student preparation for our course in organic chemistry for pharmacy students.

The formation of this adduct was first reported by Middleton, *et al.*,[1] using tetrahydrofuran as a solvent; later, Schimelpfenig[2] employed the reaction in benzene as a lecture demonstration. We use a mixture of these solvents to reduce the volume of the reaction mixture and yet provide a system in which the adduct is insoluble.

We discuss in the prelaboratory session a simple mechanism of the Diels-Alder reaction which includes the formation of a pi-electron complex. It is pointed out that the green color observed in this reaction could be such an intermediate, but that the issue has not been proven. The discussion also covers formation of other pi-electron complexes by tetracyanoethylene with aromatic systems. A variety of these are mentioned (with color photographs) in a *Chemical & Engineering News* special feature article.[3]

Using the parent structure 9,10-ethanoanthracene,[4] we named the product 9,10-dihydro-11,11,12,12-tetracyano-9,10-ethanoanthracene. A name based on bicyclooctane was also devised, and a tinkertoy model prepared to illustrate the unusual structure and to point up the basis for naming.

The Experiment

A solution of 1.3 g anthracene is prepared in 100 ml benzene contained in a 250-ml beaker. A freshly prepared solution of 0.7 g tetracyanoethylene in 5 ml of tetrahydrofuran is then added. Immediately a dark green color forms which soon begins to fade. As the color fades, a flocculent precipitate of adduct forms; in less than 10 min, with only occasional agitation, the green color has disappeared and precipitation is complete. The precipitate is filtered with suction and then recrystallized from a minimum amount of acetone. The yield of once-recrystallized material is about 80%. It melts at 263°(d) (sealed tube); reported 268–270°.[1]

An Improved Synthesis of 2-Bromonaphthalene

An improved synthesis for the large scale preparation of 2-bromonaphthalene has been developed. Of the two usual methods of preparation used in our laboratory to prepare this necessary intermediate (*1*) that of Newman and Wise (*2*) has been discontinued due to the necessity of using the carcinogenic 2-naphthylamine (*3*) and due to the rather vigorous evolution of gas upon addition to a hot flask of the complex salt, $(C_{10}H_7N_2Br)_2 \cdot HgBr_2$. Just recently we had a violent explosion on attempting to vacuum dry a 5-lb quantity of the mercury salt at 30°. The method of Wolfe and Doukas reported in THIS JOURNAL (*4*), which employs 2-naphthylamine-1-sulfonic acid, is adaptable to large scale reactions (2 moles) and affords yields of about 50%.

We found, however, that the 2-bromonaphthalene product resulting from this synthesis would only form a Grignard reagent in about 15% yield as determined by titration (*5*). It is interesting to note that a commercially prepared 2-bromonaphthalene purchased for use in this laboratory also formed the Grignard reagent in fifteen percent yield. An elemental analysis[3] was obtained on this commercial product which indicated a 3:1 ratio of 2-chloro:2-bromonaphthalene.

It was reasoned that upon addition of the diazonium chloride to a solution of CuBr in HBr there would be equilibration of Cl^- with CuBr and both CuBr and CuCl would be present. Hence a mixture of 2-chloro and 2-bromonaphthalene would result.

Fieser and Fieser state (*6*) that HCl is not as satisfactory an acidifying agent as H_2SO_4 for converting a diazonium salt to a phenol because the diazonium salt group may be replaced in part by halogen. It is also stated in this reference that for preparation of a bromide by the Sandmeyer reaction, the amine is diazotized in H_2SO_4 and the resulting aryldiazonium sulfate treated with a solution of CuBr in excess HBr. This suggests that the presence of chloride ion during the preparation of an aryl bromide from an amine might cause some of the intermediate diazonium salt to be converted to aryl chloride.

The proposed mechanism of Cowdry and Davies is as follows (*7*):

$$Ar\overset{+}{N}{\equiv}\ddot{N}\,Cl^- + CuCl \rightarrow Ar\ddot{N}{=}\ddot{N}^+ + Cl{-}\overset{-}{Cu}{-}Cl$$

$$\downarrow \text{slow}$$

$$ArCl + N_2 + CuCl \leftarrow \left[-Ar-\ddot{N}=\ddot{N}-Cu \begin{matrix} Cl \\ Cl \end{matrix} \right]$$

If the CuCl were replaced by CuBr the bracketed intermediate would be

$$\left[-Ar-\ddot{N}=\ddot{N}-Cu \begin{matrix} Cl- \\ Br \end{matrix} \right]$$

and obviously both ArCl and ArBr would result from its decomposition.

Gas chromatographic analysis of the products obtained using methods *A*, *B*, and *C* (see experimental section) were consistent with the above statements.

By altering the method of Wolfe and Doukas to exclude any chloride ion we were able to synthesize 2-bromonaphthalene (in comparable yields) that afforded a Grignard reagent in about 85% yield. This is in agreement with the value given in Kharasch and Reinmuth (*8*).

Preparation of 2-Bromonaphthalene

Method A.[5] The method of Newman and Wise was followed exactly using double quantities. Yield: 76.2 g (52.6%); mp 54–6°. On gas chromatographic analysis[4] a sample showed only one peak at an elution time of 17 min, corresponding to 2-bromonaphthalene.

Method B. The method of Wolfe and Doukas was followed exactly. Yield 197.5 g (47.7%); mp 56.7°; analysis calculated for $C_{10}H_7Br$: C, 58.00; H, 3.41; found: C, 69.27; H, 4.15. This analysis is consistent with 3:1 ratio of 2-chloro:2-bromonaphthalene. On gas chromatographic analysis[4] a sample showed two peaks, one at elution time of 11 min, corresponding to 2-chloronaphthalene, and one at 17 min, corresponding to 2-bromonaphthalene. The areas traced indicated 78% 2-chloronaphthalene and 22% 2-bromonaphthalene.

Method C. A solution of 82 g (2.05 moles) NaOH in a total aqueous volume of 3600 ml was prepared in a two gallon jar. To this was added, with stirring, 446 g (2.00 moles) 2-naphthylamine-1-sulfonic acid. An aqueous solution of 138 g (2.00 moles) $NaNO_2$ was then added and the solution was filtered through a fluted filter paper. The filtrate was then added slowly, with stirring, to 1 l of 37% HBr in a five gallon jar. The temperature was kept below 5°. This was filtered with suction and the precipitate was washed with 2 l of ice water.

Grignard Reagent Titration

Sample from method	H_2SO_4 (ml)	N H_2SO_4	NaOH (ml)	N NaOH	Aliquot (ml)	Total vol. Grignard (ml)	2-Bromo-naphthalene (moles)	Grignard reagent formation (%)
A	10.00	0.834	10.10	0.806	1.00	180.0	0.40	90.0
B	10.00	0.454	17.85	0.242	1.00	250.0	0.40	13.8
C	10.00	0.454	12.78	0.242	1.00	300.0	0.50	86.7

During the above slow addition, CuBr in HBr was prepared exactly as in the literature (*9*). The damp diazonium salt precipitate was added portionwise with stirring to the CuBr in HBr in a five gallon jar. After a vigorous evolution of N_2, the solution was heated to 90–5° on a steam bath, and filtered while hot.

To the filtrate in a 4-l beaker was added 450 g KBr with stirring. The resulting paste was allowed to cool to room temperature, filtered, washed with 1 l 20% KBr, and air-dried overnight.

The air-dried solid was added to 800 ml concentrated H_2SO_4 and 800 g crushed ice in a 5-l one-neck round-bottom flask equipped with a water condenser and heated under reflux for 14 hr. After cooling to room temperature the mixture was poured onto 2 kg of crushed ice, and extracted with 3 l of benzene. The benzene layer was washed with water until neutral to litmus paper, concentrated and distilled (4.5 mm): yield 232.3 g (56.2%); bp 122–7°.

The product was dissolved in 1 l of *n*-hexane and allowed to drip through a column packed with 2-in. basic alumina over 2-in. acidic alumina. The column was eluted with a second liter of *n*-hexane. The solvent was removed in a flash evaporator, and the product was dried overnight in a vacuum desiccator. Yield 229.5 g (55.5%); mp 54–6°; analysis calculated for $C_{10}H_7Br$: C, 58.00; H, 3.41; Br, 38.59; found: C, 58.02; H, 3.49; Br, 38.57.[6] On gas chromatographic analysis[4] a sample showed only one peak at an elution time of 17 min, corresponding to 2-bromonaphthalene.

Simple Method for the Preparation of 2,4-Dinitroaniline

The standard practical organic textbooks either do not give a procedure for the preparation of 2,4-dinitroaniline from 2,4-dinitrochlorobenzene or state a method which involves gaseous ammonia.[1] The use of ammonia gas is inconvenient for the preparation by a large class of students because of the limited number of fume hoods and ammonia sources. The author found that 2,4-dinitroaniline could be conveniently prepared by refluxing 2,4-dinitrochlorobenzene in an alcoholic solution with the readily available concentrated ammonia solution.

2,4-Dinitrochlorobenzene 2,4-Dinitroaniline

Procedure. Dissolve 2 g of 2,4-dinitrochlorobenzene in 25 ml of alcohol denatured with methanol[2] in a 250 ml conical flask and then add 10 ml of ammonia solution (sp gr, 0.880). Connect the flask to a water condenser, the top of which is covered by an inverted 50-ml beaker, and reflux the mixture on a water bath at 80° for two hours. Then add an additional 10 ml of the ammonia solution and continue to reflux for another hour. After removing the flask and cooling the contents, collect the bright yellow crystals with suction and wash them with 5 ml of the cold denatured alcohol. Recrystallize the 2,4-dinitroaniline from a mixture of the denatured alcohol and water. Filter the crystals with suction and dry them below 90°. In this way 1.5 g of product melting at 178–180° are obtained.

Laboratory Cylinder-Mill for Small Samples

Most laboratory workers have been confronted at one time or another with the problem of preparing a small quantity of powdered solid. In the smallest ball mill jars, a gram or two of material is just about enough to coat the balls and wall, and little size reduction occurs after extended periods of rotation; also, recovery of the charge is difficult. This problem has been solved in our laboratory by the design of a small mill that can grind as little as a half gram of coal or other solids; and when opened, the entire volume is easily cleaned.

Figure 1. Cylinder mill.

In principle, the mill is a rotating thin cylinder in which smaller cyclinders roll. The rolling cylinders are in contact, and a differential grinding action takes place between them as well as crushing between them and the periphery of the mill. Figure 1 shows the tempered Nitralloy cylinder halves. When they are bolted together, a 3-in. by $^{27}/_{32}$-in. cavity, having a volume of less than 100 ml, is formed. The mill is rotated by the assembly shown in Figure 2. A small gear reduction motor[1] drives a pulley set which rotates the mill arbor. Speed control between 0 and 120 rpm is provided by a 500 W bench type variable voltage transformer in the power line to the motor.

For convenience of assembling and removal of the mill from the drive system, a handle is bolted to the cover plate. The extension on the other half of the mill fits into a hole in the base plate. The motor and arbor support block are mounted on a steel base plate. The entire unit can be placed inside a dry box.

The sample (for example 0.5–10 g of 60-mesh coal) is placed in the right half of the mill; one to four Burundum®[2] grinding cylinders are placed upright; and the halves are bolted together. The halves are always oriented toward each other in the same manner by alignment of the dowel index and hole. The assembled mill is snapped into the drive shaft, and rotation is started. The speed is slowly increased to a point where the cylinders roll smoothly without lifting and dropping. After grinding, the mill is removed from the drive shaft, placed in a horizontal position, and opened. The sample is removed easily; the interior can be cleaned with a camel's hair brush. At the end of a 4 hr grinding, all of a coal sample is usually finer than 325-mesh.

Commercial Burundum cylinders are approximately $^{13}/_{16}$ in. × $^{13}/_{16}$ in. There is some small size variation in a particular lot, so some care should be taken in selecting the cylinders used. If too long, they will bind against the end plates and not roll freely. The undersize length is not critical, but should be a reasonably good fit so that the cylinders will not tilt and bind. In the design presented here, a clearance of $^{1}/_{32}$ in. is provided. Care should be taken in the machining to provide the $^{3}/_{32}$-in. radius corner on the internal circumference of the mill. This conforms approximately

Figure 2. Mill assembly.

to the curvature of the cylinder and eliminates a potential dead volume. Cylinders made of steel, brass, or other materials can be used.

The unit described has been in continuous use for about 5 years and its popularity has prompted the construction of additional units. Engineering drawings are available from the authors.

Acknowledgment is hereby made to the Bureau's Engineering Design staff at Bruceton, Pennsylvania, who worked out the many small construction details.

Organic Semiconductors

An organic semiconductor may be defined as a structure containing an appreciable number of carbon-carbon bonds and which is capable of supporting electronic conduction in the manner of inorganic semiconductors (*14*). The history of the study of photoconduction in poorly-conductive organic compounds goes back to the turn of the century. Photoconductivity in solid anthracene was discovered by Pocchettino (*32*) in 1906. At this time attempts were made to relate the phenomenon to the external photoelectric effect, but Volmer (*39*) showed that photoconduction in anthracene sets in at 4000 Å (*ca.* 3 ev), whereas actual ejection of electrons is only observed below 2250 Å (5.5 ev). The existence of a small but measurable dark conduction in anthracene was reported, and it was noted that the conductivity in the molten state was greater than that in the solid state. After the appearance of a spate of papers on the subject in the years just before 1914 (*15*), interest in organic semiconductors seems temporarily to have lapsed. In the years between the wars, a certain amount of work was done on photoconduction in organic dyestuffs, with particular reference to the part played by these in the "sensitization" of photographic emulsions (*37*). In 1941 Szent-Gyorgi suggested that the transfer of pi-electrons from molecule to molecule might play an important role in the fundamental physical processes of living organisms and this provided considerable stimulus in the study of organic semiconductors (*36*). Szent-Gyorgi later reported the existence of photoconduction in certain dyed proteins as evidence supporting his suggestion (*44*). In succeeding years there has appeared a considerable number of papers on the subjects of conduction and photoconduction in organic materials. In 1948 it was reported (*15*) that the conductivity of the phthalocyanines is an exponential function of the temperature, as is the case for many inorganic semiconductors. More recently the use of anthracene for crystal counters in nuclear physics has promoted the study, first, of photoconduction and then of dark conduction in this material. During this time, the possible biophysical implications of organic semiconduction seem constantly to have been in men's minds (*48*). The theories of photosynthesis proposed by Calvin and his co-workers appeal to "photoconduction" in the sense that light has to be absorbed at one point, at which it is used to promote some oxidation-reduction reaction. Indeed, photoconduction has been detected in chlorophyll *in vitro*. At any rate, as a result of an extensive series of investigations of a large number of materials, it is now clear that semiconduction (in the sense of a low conductivity which increases with increasing temperature) and photoconduction are common, if not perhaps universal, attributes of organic materials containing closed rings of alternating double and single bonds (delocalized electrons, conjugation), and of some other materials of less specific structure (such as proteins and technical polymers) as well.

Nature of Organic Semiconduction

Let us state exactly what phenomena are in question. We are concerned with charge transfer in a bulk sample—preferably a single crystal—whether stimulated thermally or optically. For such transfer to occur, electrons (or possibly protons) must actually move from molecule to molecule—not just around a closed ring or down a long molecular chain. Unfortunately this distinction is seldom made clearly in the literature (*18*), and so a few comments may be in order. The pi-electrons in benzene may be considered, in the zeroth approximation that ignores exchange effects, to form a half-filled zone. If a steady magnetic field is applied in a direction perpendicular to the ring, the electronic states will shift in such a way as to give rise to a net diamagnetic moment associated with the ring. We may, however, look at this in another way, which is more revealing for our present purposes. During the

Presented in part at the Fourth Summer CACT Conference, Asilomar, California, August, 1962. The previous two papers on this topic (Electronic Interpretations of Physical Properties) appeared in THIS JOURNAL, **39**, 596 (1962) and **40**, 489 (1963).

process of application of the magnetic field, an emf is induced in the ring. In the presence of the field there is a net component of "crystal momentum," ρ, clockwise or counterclockwise as the case may be—that is to say a net current flowing around the ring. The electrons of positive ρ have slightly higher energy than those of negative ρ, but, since the separations between the individual electronic levels are quite large (several ev), there are no immediately accessible states into which the electrons of positive ρ may go. In other words, there is no dissipative mechanism; and, from the point of view of electron flow around the ring, benzene is not a semiconductor, but a *superconductor*. On this basis it is possible quantitatively to account for the observed diamagnetic anisotropy in benzene, and this has been extended to the higher conjugated aromatic hydrocarbons. The reason why many of these materials in fact show *semiconducting* properties in the crystalline state cannot, therefore, be sought within the molecule itself. The "slow step" in the conduction process has to be the actual transfer of electrons from molecule to molecule; and this is a problem for which as yet no adequate theoretical treatment exists, although a modified electronic-band model has been successful in explaining some experimental transport properties, as will be shown below. A macromolecular material for which a single molecular orbital wave-function may be written for an entire crystal or crystal domain has seemed a promising approach to bulk charge transfer, therefore, in organic compounds (*45*).

The major goal of present research programs is to understand the mechanisms of electronic conductivity in such materials and to relate these mechanisms to the physical-chemical structure of the solid. While the present state of this understanding may be compared to that of inorganic semiconductors of about 35 years ago (*40*), the intriguing possibility of "tailoring" the electrical properties through organic chemistry is reason enough for substantial research activity. It is possible, currently, to develop a wide range of mechanical properties in organic solids through preparation of specific molecular structures. If this same variety can be extended to electrical parameters, the scope of semiconductor applications is likely to be expanded far beyond that made available by use of the two commercially important inorganic semiconductors, silicon and germanium, and of the inorganic semiconducting compounds like gallium arsenide.

Various organic materials display feeble electrical conductivity that increases with increasing temperature, and may also demonstrate photoconductivity. Semiconducting organic solids fall into two major categories: well-defined substances (molecular crystals and crystalline complexes, isotactic and syndiotactic polymers, etc.) and disordered materials (atactic polymers and pyrolytic materials).

Molecular Crystals

The classical example of a molecular crystal is anthracene, which is probably the most extensively studied organic semiconductor. There is now experimental evidence that some of the transport properties of anthracene are not unlike those familiar from studies on silicon and germanium. Hole and electron mobilities of the order of 1 cm^2/v-sec can be measured in zone-refined crystals. These drift-mobility experiments employ photoconductivity, since the crystal is a poor conductor in the dark. There is also experimental evidence that carriers are produced only on the surfaces or at electrodes by excitation waves (or "excitons") generated at the point of photon absorption. These experimental transport properties can be explained on the basis of a *modified* electronic-band model of solids. Calculation of the width of the energy bands proceeds by computing overlap integrals between pi-electron molecular wave functions on adjacent molecules. Because the intermolecular binding is weak in molecular crystals, the overlap is small and leads to narrow energy bands, which implies small carrier mobilities. The calculation is also successful in accounting for observed mobility-anisotropies. This demonstration of the success of a band model in explaining transport properties in organic semiconductors is comforting in that many of the concepts developed for inorganic materials are immediately applicable. Less comforting is the equally important conclusion that in order to observe the basic properties of the customary "small-domain" organic crystals, purification techniques as extensive as those applied to inorganic materials must be applied. Nevertheless one may still hope that useful semiconducting properties might be discovered among "large-domain" organic semiconductors without such careful processing. Zone-refined anthracene single crystals are nearly free from space charge effects due to carrier trapping and furthermore can show *electronic* (n-type) conductivity. Only hole-conduction and many trapping effects were always observed in less pure crystals and have contributed to confusion in experimental results in the past.

Mechanisms for Semiconduction

The exciton states of the simpler aromatic solids have been examined (*8*, *9*, *11*, *12*, *15*, *28*) in the quest to understand organic semiconduction. In these compounds the absorption spectra of the crystals and of the corresponding free molecules are very similar. This suggests that the final state of an optical transition in the solid is essentially a molecular excited state. However, there are features of the crystal spectra which can be explained qualitatively and quantitatively if one assumes that the molecular excitation is not confined to one molecule but is coherently shared by all molecules of a perfect crystal. In such a state—an exciton—the excitation energy and crystal momentum is definite but the position of the exciton is completely uncertain; i.e., it may be considered delocalized. In a classical description of an exciton in a molecular crystal, one may consider the excitation to be mobile, with the electrons involved in the excited state of a particular molecule remaining behind as the excitation passes. In contrast, the classical picture of the exciton in a conventional semiconductor (germanium, silicon, etc.) is that of an electron and hole bound together to form a hydrogen-like atom which moves freely through the crystal carrying along the excitation energy (*41*). In a more general formulation (*13*) of the exciton problem, some of the kinetic energy terms are matrix elements in which there is a transfer between the initial and the final state, of both the excitation and the charges involved in this excitation from one molecule to the next.

Such charge exchange cannot be in the electronic wave functions of neighboring atoms or molecules are isolated from one another, as is the case in crystals like anthracene. On the other hand, where the overlap is large, the charge exchange is very important, but then the use of atomic or molecular orbitals in building crystal wave functions becomes inaccurate. In such cases one may reformulate the problem, obtaining the well-known model of a bound electron-hole pair moving through the conventional semiconductor (*41*).

One may also transfer excitation primarily through an electric interaction between the transition dipole moments of the molecules. These transition moments are the same as the matrix elements involved in optical absorption, so the interaction is large and the effective mass of the exciton is thereby small if the absorption is strong. The classical model (*41*) is most accurate where the binding between the electron and hole is weak, so that the exciton radius is large. With the electron far from the hole, the optical transition dipole moment will be small so that in crystals like germanium this second mechanism for motion of the excitation may be neglected. On the other hand, aromatic molecules generally have fairly strong optical absorptions, so the second mechanism is important; excitons corresponding to the second anthracene transition have a range of kinetic energies of the order of 1 ev, as have been found experimentally (see above).

A model, similar to the one-electron band model classic to inorganic semiconductors (*19*), may be applied to the *perfect* aromatic molecular crystal (*35*). The free electron will spend most of its time in the neighborhood of one molecule or another, and very little time in the interstitial regions; its wave function will be a linear combination of excited molecular orbitals. Because these orbitals are almost completely isolated from one another, the effective mass of the charge carrier will be large. Free hole states can be treated in a similar fashion. In the case of the excitons, the strong excitation transfer mechanism in aromatic crystals makes up for the weak pair transfer, so that the exciton effective mass may still be small. No such alternative mechanism is known for the conducting states. With a large effective carrier mass, the range of kinetic energies will be of the order of, or much smaller than, kT at room temperature. These kinetic energies may then be smaller than the perturbation energies, so that the model of a free carrier occasionally scattered by imperfections is not valid. With a sufficiently large effective mass in the perfect crystal, a better picture is provided by the "hopping model," in which one assumes that the carrier spends a long time on some molecule; the perturbations arising from the presence of other molecules cause an occasional jump to a neighbor. For intermediate values of the effective mass, it is possible that neither the hopping nor the conventional band picture is valid. To find the excitation energy for the lowest conducting state in the hopping model, one may start with a neutral crystal, remove an electron from one molecule, and place it on another a great distance away (*11*, *28*). Considering this charge transfer to take place in several steps, we first remove the electron from its original molecule to a point far from the crystal; this requires the addition of energy I, the molecular ionization potential. Bringing the electron back to the crystal and placing it on the second molecule regains the energy A, the molecular electron affinity. We now have a widely separated ion pair, and each ion polarizes the surrounding molecules. The energy, W, of interaction of each ion with the polarization is the same for the two ions, approximately. The excitation energy is then $I - A - 2W$. There are other minor terms, of course. Either the electron on the negative ion or the hole left behind on the positive ion may now carry current, by hopping to adjacent molecules. The two charges are sufficiently far apart that they act independently of one another.

Where the optical transition moments for molecular crystals are very small, therefore, one should use a hopping model for the excitation, especially for excitations to the molecular triplet state where the optical transition is highly forbidden. The hopping model is also applicable to such excitations as the O-O component of the first benzene transition, except possibly in a good crystal at very low temperatures (a forbidden transition in the free molecule, but weakly allowed in the crystal). Another excitation in which the hopping model is useful is one in which an electron is transferred to an *adjacent* molecule, leaving a hole behind (*28*). The attraction between the two charges prevents further separation, if no additional energy is supplied. To move this excitation through the crystal, one must also transfer the charge pair. The matrix element for this process is extremely small, and the hopping model should be used, probably even at low temperatures (*29*).

In each of several aromatic crystals, the observed value of the activation energy for dark conductivity, E, turned out to be $^1/_2E_t$, where E_t is the energy of the triplet state of the isolated molecule, measured from the ground state, and E is defined by the first of the following relations:

$$\sigma = \sigma_0 e^{-E/kT} = \sigma_t e^{-E'/2kT}$$

with T the absolute temperature, k the Boltzmann constant, σ the dark conductivity, and σ_0 a constant. The quantity E', introduced to simplify later discussion, is defined as $2E$. The similarity between the last member of the above relations and the expression for the dark conductivity of a conventional intrinsic semiconductor (*19*) led some investigators to assume that E' was the band gap in aromatic crystals. The observed equality between E' and E_t led to the further assumption that the molecular triplet state was involved in the conduction. Since this state is nonconducting, the involvement must be indirect. The validity of the first assumption depends on whether the conductivity is intrinsic; this point has been dealt with by Garrett (*15*); others have shown that the triplet state actually can play no role in organic semiconduction (*11*, *12*). In thermal equilibrium, the population of each conducting state depends on the energy of that level, but not on the mechanisms of transitions between states. The observed value of E' therefore cannot be explained in terms of the excitation of one of the nonconducting states (in particular, the triplet state of a molecule), followed by a transition to the conducting state. If the equality of E' and E_t is not a coincidence, it must arise from a relationship between the structures of the triplet and conducting states. It has been suggested

that it takes the same energy to raise an electron from the highest filled to the lowest unfilled molecular orbital (with the final spin state a triplet) as it does to place that electron in the same unoccupied state of a distant molecule. When the latter transfer is effected, either the electron or the hole left behind on the first molecule is free to move from one neighbor to another. The population of charge carriers would then have the temperature dependence indicated in the relation above, with the "band gap" E' numerically equal to E_t. One might, as an approximation, use the same molecular wave functions, in the two cases, for the state which the electron enters. But even if the wave functions were identical, the two excitation energies would not be the same. For spinless electrons, the transfer of an electron to a distant molecule involves, among other energy terms, the Coulomb energy of separation of the electron from the positive charge left behind. This contribution, which is not negligible, does not appear in the energy of the triplet state. Second, when the spin is taken into account, we note that each of the two ions produced by the charge transfer is in a *doublet* state; the wide separation of the ions prevents these states from interacting to form a singlet and a triplet. Since the singlet and triplet molecular states differ greatly in energy, there is no reason to expect equality between the energy of the molecular triplet and that of the two ionic doublets. Next, let us assume that for some unknown reason, each set of measurements was carried out on a sample in which there was an equilibrium number of triplet excitations but an abnormally low number of charge carriers. For such a nonequilibrium case, one can set up a rather artificial model in which the current is indirectly determined by the population of the triplet states. This number, however, varies with temperature as $e^{-E_t/kT}$, *not* as $e^{-E_t/2kT}$. If, for this or any other reason, the current were proportional to the triplet population, one should find E, and not E', equal to E_t (in anthracene at room temperature the factor $e^{-E_t/kT}$ is so small that there is a negligible probability of finding even a single molecule in the triplet state); if even the triplet states are not in equilibrium, there should be *no* relationship between E' and E_t. It should also be noted that the factor of $^1/_2$ in the exponent in the case of an intrinsic semiconductor appears because the possible distributions of electrons in the conduction band are independent of the distributions of holes in the valence band. This factor appears also in the case of an equilibrium distribution of ion pairs. However, in molecular excitations, once one determines a distribution of electrons among the excited states of the various molecules, the distribution of "holes" in the ground states is completely determined. In such a case, the factor of $^1/_2$ does not appear. These conclusions are based on some rather general statistical arguments, not restricted to solids. It is required only that the Fermi level (*46*) be far, compared to kT, from any of the one-electron states.

The spacial distribution of trapped charge in anthracene has been subjected to analysis (*21, 33*), and evidence has been presented that indicates that most of the free electrons are injected into the anthracene at the negative electrode and that anthracene is an extrinsic rather than intrinsic photoconductor. If correct, electron-injection is an exponential function of which indicates that the anthracene-metal contact may form a *p-n* junction (*19*).

Charge-Transfer Complexes

A charge-transfer complex is an intermolecular addition compound, composed of an electron-donor (e.g., an aromatic hydrocarbon) and an electron-acceptor (e.g., a halogen). In passing from anthracene to the charge-transfer complexes, we go from one extreme in which the optical evidence for delocalized charge is limited or absent to the other in which electronic delocalization effects are so strong as to overwhelm the optical properties associated with the private molecular energy levels. The metastable $(Perylene)_2(I_2)_3$ and $(Pyrene)(I_2)_3$ complexes (*24*) and the unstable bromine-perylene complex (*3*) show relatively high conductivities (0.01 to 1 mho/cm at room temperature); and they are optically opaque in thicknesses (down) to 1000 Å in the near-infrared, visible, and near-ultraviolet. The activation energy for conduction of these complexes is fairly low (0.14 to 0.01 ev). Labes (*26, 27*) showed that the unpaired-spin concentration in these complexes varied from 10^{18} to 10^{19} cm^{-3} and that, on changing the temperature, the density of unpaired spins changed in the same way as did the conductivity (below 200°K, where the activation energy for conduction in pyrene became altered, the unpaired-spin concentration became temperature-independent). This suggests, as with anthracene, that the major part of the temperature-dependence of the conductivity comes from a change in the carrier *concentration* rather than from any change in mobility. The absolute values for mobility demanded by a comparison of conductivity and spin-resonance data are in the vicinity of 10^{-2} cm^2 $volt^{-1}$ sec^{-1}. Therefore, in these materials, the carrier density at room temperature must be of the order of 10^{14} to 10^{15} times that prevailing in anthracene, each carrier having, however, a mobility of the order of 100 times less.

Quite large conductivities, as high as 100 mho/cm, can be developed in other molecular crystals in which molecular complexes consisting of chemical groups which are electron donors are combined with groups which act as electron acceptors. The electron exchange between such groups has the effect of producing many nearly free carriers and yielding high conductivity even with very small carrier mobilities (usually less than 10^{-2} cm^2 v-sec). The electrical properties of some molecular complexes are nearly metallic-like in many respects, showing degeneracy effects and small or negligible activation energies for conductivity. There is some preliminary evidence that the band model is applicable here also and that again the crucial point is the overlap of electronic wave functions between molecules. The other features of the band structure—e.g., the width of the forbidden gap—are related to the energy levels of the isolated molecule, although intermolecular interactions may not be neglected. It is interesting to note the analogy between the donor-acceptor action of chemical groups in the molecular complexes and the behavior of impurity atoms in germanium and silicon. Recently an interesting new set of compounds having higher electronic conductivity than any others reported has been announced (*1, 2, 4, 6, 7, 16, 17, 23, 30, 43*) by workers at

DuPont. These are charge-transfer complex salts of the radical anion of tetracyanoquinodimethane,

and have the generalized structure $M^+(TCNQ^-)$ (TCNQ), where TCNQ is tetracyanoquinodimethane and $TCNQ^-$ is the radical anion

while M^+ is a cation, usually organic, such as the triethylammonium ion. In a few cases, compounds lacking neutral TCNQ have been formed; for example, 5,8-dihydroxyquinoline with TCNQ gave the anion-radical salt, $C_9H_7NO_2H^+TCNQ^-$, resistivity (powder) = 14 ohm-cm. However, quinoline with TCNQ gave $C_9H_7NH^+(TCNQ^-)(TCNQ)$, resistivity (single crystal) equals 0.01 ohm-cm. These complexes have an electron density of one free electron per molecule, and a resistivity of the order 0.01–100 ohm-cm, depending on direction (the electrical resistivity is highly anisotropic along the three principal crystal axes). For comparison, the resistivity of hyperpure silicon is about 1000 ohm-cm, graphite about 10^{-3} ohm-cm and most organic compounds 10^{10}-10^{14} ohm-cm. (The lowest resistivities *previously* reported for organic compounds were those for the metastable halogen-perylene complexes (*3*, *24*).) The electron mobility seems to be very low, although so far only incomplete data (*5*) have been published. The thermoelectric power of about -100μV/°C is characteristic of a good metallic conductor.

A preliminary theoretical interpretation of these phenomena has been developed (*5–7*). In both types of TCNQ salts the band formed from the lowest normally unfilled MO of TCNQ is partially filled, being half filled for the first series of salts (M^+TCNQ^-) and 1/4 filled for the second. As a result of the relatively weak intermolecular interactions characteristic of molecular crystals, this band will be quite narrow. In addition, both the bandwidth and the exchange coupling of the odd electrons (*6*, *7*) appear to be strongly influenced by the nature of the cation, M^+, and by whether or not TCNQ° is present in the crystal. In the quinolinium salt (see Table 1), the electrons of the ($TCNQ^-$) radicals appear to form a conventional degenerate system similar to a metal. This is evidenced by the very large electrical conductivity, the virtual absence of activation energy for conductivity, and a temperature-independent paramagnetism. The activation energies of the other salts are also low and are isotropic within experimental error although the electrical conductivities are highly anisotropic (the triethylammonium salt has room-temperature values of 4.0, 0.05, and 0.001 mho/cm in the three principal crystal directions, and these vary exponentially with temperature with an activation energy of 0.14 ev). Preliminary crystallographic data show that this salt belongs to the monoclinic C2 space group with four TCNQ formula units per unit cell. The TCNQ units appear to be arranged in infinite face-to-face stacks with the direction of highest conductivity lying along these stacks and approximately normal to the planes of the TCNQ molecules. The thermoelectric power (see above) is in the direction of highest conductivity and this indicates that electrons are the majority carriers in this materials. No Hall voltage has been detected in this salt and this, together with the observed conductivity and the assumption that all of the electrons in the radical-anions participate in carrying the current, leads to the conclusion that the electron mobility in it lies between 0.02 and 0.04 cm²/v-sec. It is possible that charge carrier motion in these materials takes place by an activated hopping process, in which case it is questionable whether a Hall effect should be observed at all, but I feel this interpretation is not as likely.

TCNQ is a strong pi-acceptor. ESR studies (*6*, *7*) show a spin correlation between magnetic electrons in these salts, giving rise to a ground singlet state and a *thermally accessible* triplet state. Typical *S-T* separations (*J*) found are: 0.034 ev for the triethylammonium salt, 0.062 ev for the triphenyl phosphonium and the triphenylarsenium salts, and 0.41 ev for the morpholinium salt. The importance of paramagnetic impurities in studies of the magnetic properties of organic solids must be emphasized. A per cent or so of doublet-state impurity species can dominate resonances near g = 2.002 in molecular solids obeying *S-T* ($S_1 - S_3$) statistics.

(For a strong donor and strong acceptor, as here, complete electron transfer could occur and the system could be expected to exhibit paramagnetic characteristics in the ground electronic state. In the solid, interactions are more extensive than in solution (single molecules in solution) and than pairwise and could provide an electron-conduction mechanism.)

In these salts, M^+ is diamagnetic and $TCNQ^-$ or $(TCNQ)_2^-$ are paramagnetic, and EPR characteristics are attributable to the presence of entities residing in the triplet rather than doublet electronic states. The best model to date (*6*, *7*) shows M^+ forming insulating layers separating adjacent two-dimensional layers of the stacked TCNQ's (face-to-face stack). Formally there are 2 "molecules" per unit cell, i.e., 2 M^+, 2 $TCNQ^-$ and 2 TCNQ°. Evidence has been presented for a model in which triplet electrons exist in an extended pi-system which allows effective distance of separation of electrons larger than for naphthalene and indicates

Table 1. Electronic Properties of Some Radical Anion Salts

Material	Electrical conductivity, mho/cm at 300° K	Activation energy, E_A, in ev
 $[TCNQ\cdot]^{\ominus}$ (TCNQ)	100[a]	<0.01
$(C_2H_5)_3\overset{\oplus}{N}H(TCNQ\cdot]^{\ominus}$ (TCNQ)	4.0[a]	0.14

that the triplet state entity is confined to the vicinity of the TCNQ molecules, *with M^+ functioning mainly as a crystal-field source;* the triplet electrons are not considered as residing on a single TCNQ molecule. Thus the triplet entity is probably at least two TCNQ units, and the electron-pair giving rise to the triplet state may be distributed over all four TCNQ units in the unit cell.

Polymers

The semiconducting properties of the polymers and similar organic compounds are not nearly so well established as those of the molecular crystals, partly because their physical-chemical structures are not so well characterized. Such materials are usually insulating, but appreciable conductivities can be developed by modification through chemical synthesis or pyrolysis and some 100 different types have been studied. Conductivity activation energies ranging from essentially zero to several electron volts and conductivities from insulators down to within an order of magnitude of 10^2 mho/cm are reported (*47*). Carrier mobilities are very low and these solids are almost always *p*-type. Some evidence exists for chemical impurity effects and zone-refining techniques have been applied to a few compounds. A correlation of experimental measurements of conductivity and thermoelectric power as a function of temperature can be made on the assumption there is possible intrinsic semiconductivity. However, there is no evidence that a band model is applicable to the polymers and the intrinsic picture results in some inconsistencies. Also, interpretations of experimental conductivity activation energies in terms of band-model energy gaps, while quite common, are, as shown above, largely unjustifiable. The lack of an observable Hall effect in nearly all specimens greatly hampers interpretations. There is as yet no clear understanding of structural effects such as the influence of chain length or the number of conjugated carbon atoms per molecule. Indeed, the actual chemical structures of the pyrolyzed polymers, in particular, are often not known (*38*).

Experimental measurements on organic semiconductors are hampered by the fact that many compounds are available only in powder-like form. It is common to study compressed pellets of these materials, which practice introduces serious intergranular effects. Also, unless these are carried out in O_2-free conditions, free radicals form. And there is some evidence for a biradical triplet-state overlap of molecular orbitals. Similarly, electrode influences perturb the experimental results in unknown ways, particularly on high resistivity specimens. In a few specific cases it has been shown that good agreement between single crystals and compressed pellets can be realized, but in other cases there are violent discrepancies between the two. Loss tangent measurements or other ac resistance techniques oftentimes applied in such situations must be approached with extreme caution, as there is no a priori guarantee that the ac losses are related to the dc conductivity.

Solid Free Radicals

The potential box model used to describe the semiconducting properties of organic substances indicates that under favorable circumstances a solid free radical would behave as a semiconductor with very small or zero energy gap and this has proved to be the case in measurements by both ac and dc methods on samples of α,α'-diphenyl-β-picryl hydrazyl (DPPH), on Coppinger's Radical and on Banfield and Kenyon's Radical (*22*). The samples included polycrystalline materials, evaporated films and single crystals. The role of odd electrons in the conduction process in crystals of substances having only partial radical character is less well understood. Indeed, since the existence of partial radical character is in many cases still not fully explained in quantitative and theoretical terms, the problem remains a complex one. Free electrons are known to exist in some polycyclic hydrocarbons like violanthrone and violanthrene, but the semiconducting properties are in no way anomalous. On the other hand, those molecular complexes that are so highly conducting (*1, 2, 6, 7, 16, 17, 23, 24, 30, 43*) are in most cases paramagnetic. Similarly there appears to be some correlation between the semiconductivity and the concentration of free electrons in pyrolized polymers. Thus, further information is required on the properties of unpaired electrons as conducting species.

The idea of conduction by electrons without activation has implications in biophysics. The conductivity of dry proteins is rather low to explain the rates of many metabolic processes in terms of electron transfer. The suggestion has been made that a protein in a suitable environment may lose a hydrogen atom during the course of a reaction, creating a free radical. This is equivalent to creating a positive hole in the conduction band and would result in a lowering of resistance. Unfortunately, the initial activation energy requirements for the creation of the free radical that is not resonance-stabilized is so high as to make this mechanism rather unlikely; the ESR signals observed in biological systems no doubt relate to the less active resonance-stabilized radicals (if we rule out photochemical systems). However, in the case of DPPH, evidence is available to show that the pi-electron, after having been excited to the lowest empty orbital, may then tunnel to the *equivalent* empty level in a neighboring molecule (the levels of the latter, as a whole being lower) closer to the positive electrode. An electron may similarly enter the resultant highest unfilled level from an *equivalent* filled level in a neighboring molecule closer to the negative electrode (and hence of higher potential), which is the same as a positive hole moving in the opposite direction. The permeability factor for the barrier to tunneling determines the mobility of the electron; the usual effects of charge separation are minimized because of the very high polarizability of the surrounding pi-electrons. Compared to charge-transfer complexes, however, the conductivity of such molecules is relatively low. Nevertheless, the existence of unpaired electrons in complexes is indicative of ground-state bonding with a large ionic component. Narrow line widths are also indicative of this strong exchange interaction. Such molecular complexes thus represent semiconductors (by virtue of their *activated* charge transport) with the following peculiarities: (1) they are very insensitive to impurities; (2) they have extremely low mobilities; and (3) they exhibit a proportional increase in thermopower with temperature up to a saturation value.

Other Types of Organic Semiconductors

As with the inorganic types, the organic semiconductors are also characterized by the nature and type of the carrier which appears to dominate in the carrying of current. A material may be either *n*-type or *p*-type, for example. Among the organic dyes investigated, the cationic dyes appear to be *n*-type semiconductors and the anionic dyes *p*-type. (The cationic dyes can exist in two forms, one of which will induce photoconductivity in the glass substrate upon which it is laid.) The phthalocyanine molecule, which is much like the active center of several biologically-active compounds (e.g., chlorophyll), can accommodate a metallic atom at its center. These molecules' conductivities range from 10^{-10} to 10^{-11} reciprocal ohm-cm. Compressed pellets of phthalocyanine, if they contain traces of certain inorganic acids, have been observed to act as rectifiers, especially if placed between metallic electrodes of two different metals. Magnesium phthalocyanine, if coated with a layer of air-oxidized aromatic amine, has been observed to produce a photovoltage when illuminated. Analogous behavior has been observed in coronene and chloranil (*25, 26*). Such behavior may indeed be much like that in certain biological systems. A large number of semiconducting polymers of the polyacene quinone radical (PAQR) type have been prepared by the Friedel-Crafts reaction and studied. The conductivities range from 10^{-4} to 10^{-10} reciprocal ohm-cm, and the Seebeck coefficients (thermoelectric power) are positive, so far as examined, being about 100 to 300 μV/°K. The E values, as calculated from the slopes of the conductivity versus T^{-1} lines, range from 0.26 to 1.8 ev. These polymers were prepared from various reactive aromatic hydrocarbons (some bearing substituent groups) and the anhydrides of various aromatic acids. The PAQR polymers are observed to contain high concentrations of stable free radicals, and are therefore polyradicals. They are hard, black, and cross-linked, but show appreciable thermoplasticity. The electrical data exhibited by them demonstrates a good fit to the equations for an *intrinsic* semiconductor; the populations of carriers so indicated is about 10^{15}/cm^3, with mobilities of about 10^{-2}cm^2/v-sec, holes having a somewhat greater mobility than electron carriers. This is not to be taken to mean that these materials are intrinsic semiconductors in the strict terms of the band theory, but rather that, mathematically, a good fit can be obtained using such equations. Upon heating the PAQR polymers to elevated temperatures in an inert atmosphere, the conductivity at first falls sharply (*ca.* 400°C) and then increases rapidly to values characteristic of polymers (over 600°C). This shows that there is something unique and characteristically favorable to conduction in the original polymers and that they are not merely pyropolymers. Polymers of related structure, called xanthene polymers, and others comprising polydiketones appear to be semiconductors roughly equivalent in conductivity to the PAQR polymers. Ferrocene, which is a sandwich-type compound having an iron atom bound between two layers of hydrocarbon groups, is an insulator. Ferrocene resembles the lower aromatic hydrocarbons in many ways. If this molecule is attached to a vinyl group and made into a polymer, it is, like polystyrene, an insulator. Polymers formed from ferrocene molecules linked intermolecularly by CO groups (i.e., the polyketones) show limited semiconduction, ranging from 10^{-3} to 10^{-11} mho/cm, whereas linking them with benzal groups gives polymers with conductivities of 10^{-7} to 10^{-8} mho/cm. Polyphenyl, a linear chain of aromatic rings, shows a conductivity of about 10^{-10}; polytetrachlorophenylthioether has a conductivity of either 1 or 10^{-7} mho/cm, *depending upon the method of preparation.* The latter compound, if placed between silver and platinum electrodes, shows rectification. Work has been reported on a vulcanized aromatic hydrocarbon type of polymer made with sulfur and aromatic hydrocarbons which exhibits a conductivity of 10^{-4} mho/cm. Copper phthalocyanine polymers with extensive cross-linking have been found to have conductivities of 10^{-4} and 10^{-8} mho/cm. The conductivity is higher than that of the corresponding monomer (see above) and is a good illustration of the efficacy of polymerization in increasing electronic conductivity. Proteins in the dry state conduct slightly, but as in the case of albumin (10^{-21} mho/cm) may be insulators. In the wet state they conduct appreciably, and it was suggested that hydrogen-ion transfer may be involved (*42*).

It has been found possible to "dope" copper phthalocyanine polymers; the sign of the Hall coefficient is observed to change with an oxygen pressure greater than 490 mm Hg (see Table 2). Thus, conversion from *n*-type to *p*-type material and vice versa can be accomplished by changing the O_2 pressure. Qualitative adsorption studies made on the material at room temperature reveal the possibility of water vapor adsorption. Other supplementary additives or dopants, when purposely introduced either in the preparation of the compound or after the compound has been formed, can alter or modify the conductivity type and thermoelectric power. See Table 3.

Among the organic structures examined in the author's laboratory for semiconductor-like behavior have been derivatives, in stressed or "unusual" electronic states, of sandwich-compounds like ferrocene. Activation energies of 0.1 to 0.3 ev have been observed,

Table 2. Effect of O_2 Pressure on the Hall Coefficient

O_2 pressure (mm Hg)	R_H (cm^3/coulomb)
10^{-5}	−252
209	−103
414	− 39
490	0
775	+105
990	+241

Table 3. Effect of Doping on the Conductivity-type of the Polymer of Copper Phthalocyanine (Measured at 23°C)

Agent, treatment or preparation	Conductivity-type	Thermoelectric power μV/deg
None	*p*	12–18
Water vapor	*n*	59
H_2S	*n*	30
Bromine	*p*	1
Ozone	*p*	5
Polymer prepared with copper-deficiency	*n*	8
Polymer prepared with excess of copper	*p*	4
Heat-treated (irreversibly)	*p*	33–37

with anisotropic conductivities in the range of that in organic semiconductors and that, in some cases, appear to observe the classical conductivity-temperature exponential relationship (*20*). In addition, a number of Hall-coefficient determinations were made and, in certain cases, highly-reproducible values were obtained. Recently (*31*) Mulay and Fox showed that on the basis of paramagnetic measurements of magnetic anisotropy the bonding in ferrocene is $d\pi$-$p\pi$ single metal-to-ring covalent bonding. Like benzene, the data supports "ring current" effects to explain anisotropy.

Conclusion

It is clear that the science has not yet progressed to the point where applications or devices using organic semiconductors can be fabricated, although rectifying contacts to organic semiconductors are well established. Thermoelectric applications can be mentioned in view of the low thermal conductivity of organic materials together with the demonstrated possibility of appreciable electric conductivity. Unfortunately these desirable properties are as yet accompanied by very low values of thermoelectric power. Many properties of these compounds are likely to depart from those familiar in inorganic semiconductor technology, which implies that different applications and devices will result (*10, 34*). In any event, the improved understanding of organic materials which results from this research, together with the development of new (particularly electrical) experimental measurement techniques, cannot fail to make substantial contributions to organic compound technology. It is well recognized that in the analogous situation the study of inorganic semiconductors has contributed much toward the appreciation of properties of other solids. The most remarkable thing about the current state of these investigations, however, is the frequent complete reversals of field in connection with current attempts to explain organic semiconduction, as new and apparently contradictory data appear. Lest the investigator become discouraged with such a state of affairs, it should be remembered that this is a stage through which most of the fruitful areas of study have passed. It is merely an indication that some experiments have not been carefully or fully performed and that many crucial and interesting experiments, rich in theoretical implications, have yet to be carried out.

If the high efficiencies of electron transfer processes now obtainable from the inorganic semiconductors can be attained with the organics (contingent, in all probability on a better theoretical understanding of the nature of these processes in organic compounds), it is possible that commercially attractive organic semiconductor devices may result. In addition, it may well be that the greatest contribution to human progress resulting from studies on organic semiconductors will be in contributions to our understanding of certain important biological processes, such as photosynthesis, initiation of photosensitive carcinogenesis, as well as processes involved in vision, which are strongly concerned with activated electron transfer in organic polymeric media (*48*). On the other hand, the added interpretations of electron-transfer processes which man could apply broadly may be most fruitful; the concepts and techniques of molecular engineering would then be applied to achieving optimum results in these materials. The possibilities we can now foresee for electronically-active polymers are many and varied. It now appears that certain semiconductive polymers have perhaps the highest known and stably-reproducible coefficient of resistance change with pressure. Use at high pressures and temperatures up to 800°C has been successful. Semiconducting polymers can be used as resistive elements having selected properties such as zero coefficient of resistance change with temperature, or a desired positive or negative change. Such polymers may potentially be useful as thermoelectric power sources. The polymeric semiconductors could be applied as anisotropic semiconductive coatings, as photovoltage sources, or possibly as photoelectric devices, for they change conductivity upon illumination. Photovoltaic cells made up of layers of magnesium phthalocyanine and air-oxidized tetramethyl *p*-phenylenediamine, or of coronene coated with a layer of *o*-chloranil, were investigated. More recently, considerable rectification was obtained from phthalocyanine layers confined by two differing metals and bearing traces of an acid. These rectifiers were operable at 60 cps and had excellent forward-to-reverse current ratios up to 500 cps. The action was proved to be electronic and not simply ionic, for long-continued passage of current did not change the conductivity. Organic materials are generally quite "ohmic" and show little change in resistance with electric field change until rather high fields are used. Among the other possible uses for organic semiconductors in electronics are as components of ferroelectric devices, of microphones, of parametric circuit elements, of hydromagnetic devices, cold-emission electrodes, or as information-storage components. It can also be suggested that semiconductive organics may find application as fuel-cell electrodes, phosphor-modifiers and coatings for color lighting, as semiconductive layers or films to heat surfaces or remove charges from them. One very promising outlook is for their use in electrically applied coatings. The possibilities seem almost as numerous as there are organic compounds.

Chem Ed

LETTERS

To the Editor:

A confusion may arise from Dr. DeWolfe's differential rate equation (1) involving the thermodynamic activities instead of the concentrations (DeWolfe, R. H., this Journal 40, 95 (1963));

$$-d(C)/dt = k\, a_A{}^l a_B{}^m a_C{}^n \qquad (1)$$

If we define the activity as γC where C is the concentration and γ activity coefficient and if we restrict ourselves to ionic reactions in solution, this equation would predict that the rate of the reaction always would decrease upon increase in the ionic strength, since the Debye-Hückel theory predicts that

$$\gamma = f(\sqrt{\mu})$$

Actually, however, it has been observed that the rates decrease, increase, or are unaffected by the increase in the ionic strength. This can be explained in terms of the absolute reaction rate theory.

Referring to the literature,[1] we find the following rate equation for the simplest reaction;

$$A + B = AB\ddagger \rightarrow P$$

$$d(P)/dt = k'K\ddagger(A)\ \gamma_A\ (B)\ \gamma_B/\gamma_{AB}\ddagger = k\ a_A\ a_B/\gamma_{AB}\ddagger \qquad (2)$$

where

$$K\ddagger = (AB\ddagger)\ \gamma_{AB}{}^*/(A)\gamma_A\ (B)\ \gamma_B$$

and

$$k = k'K\ddagger$$

Equation (2) predicts correctly, in principle, that the rate will increase for the identical charge species of A and B because AB‡ will have a double charge which decreases $\gamma_{AB}\ddagger$ still more, and that the rate will decrease upon increase in the ionic strength, if A and B are oppositely charged. If A is charged but B is neutral molecule, the rate will not change upon adding salts (the so-called Livingston's fan).[2] The present argument is in principle applicable to any organic reactions in solution which proceed via ionic mechanisms.

Equation (1) will not anticipate the effect of the ionic strength on the rate of the ionic reactions in solution, which are common in organic chemistry, except on those cases in which the reacting species are of equal and opposite charge. The essential point in this argument would not be affected by the sign of the coefficients, l, m, and n.

Equation (2) based upon the application of the Debye-Hückel theory to predict γ's is offered as a more generally applicable expression. Further, the Debye-Hückel theory can predict the effect of the ionic strength on γ_A, γ_B, and $\gamma_{AB}\ddagger$ correctly with respect to the direction of the deviation from unity within the limit of approximation, as this limitation has been frequently applied to the solution reactions.

More Wealth from Agriculture

Utilization research and development in the Agricultural Research Service of the U.S. Department of Agriculture is concerned with finding new and improved uses for farm products, so that profitable new markets for the farmer will be created and present markets expanded.

The four Utilization Research and Development Divisions—the Eastern at Wyndmoor, Pa., near Philadelphia; the Northern at Peoria, Ill.; the Southern at New Orleans, La., and the Western at Albany, Cal.—have a professional staff totaling about 850, mostly chemists, chemical engineers, food technologists, and microbiologists. Each Division operates a large regional laboratory and some Divisions have research personnel in field locations. Thus, the Eastern Division includes research scientists stationed in Washington, D. C., and Beltsville, Md. Figure 1 shows a typical installation of a modern research instrument. J. M. Purcell is shown adjusting the Eastern Division's NMR spectrometer.

Some of the accomplishments of utilization research were described in an earlier report entitled "New Wealth from Agriculture" (*1*). The present paper summarizes briefly some additional accomplishments that have created additional new wealth from agriculture.

Research in the Eastern Division Laboratory

The earlier report (*1*) described some of the Eastern Division's research program on animal fats. This program is continuing, and from it are coming new chemicals of importance in lubricants, detergents, plastics, and in other large-use industrial fields (*2*). The epoxy compounds, stemming from research on the epoxidation (*3*) of the fatty acids of animal and vegetable fats and oils, are widely used as plasticizers to give heat and light resistance to plastics.

These epoxy compounds are also found in nature. The oil in the seeds of the exotic ironweed plant (*Vernonia anthelmintica*) contains 70% epoxy acids. This plant is now being grown experimentally in many parts of the United States by agronomists, while Eastern Division scientists are studying the oil. If the industrial potential for the oil of this plant continues to develop (*4*), it may be cultivated domestically for industrial use and grown on acreages now devoted to the production of grains or other crops now in excess.

In addition to industrial products and processes utilization research seeks to develop new food products and to devise new and improved methods of making existing products. The Eastern Division has been assigned a number of important commodities used principally for food—milk, meat, eastern fruits and vegetables, maple sirup, and honey. Some of the products developed from these commodities have not only helped agriculture and industry, but have lightened the burden of the kitchen chores that must be done by the American housewife. Eastern Division engineers pioneered the development of a new way of dehydrating

mashed potatoes (*5*). Now the product of this research—known as potato flakes—is being made by 12 American factories, and is available throughout the country. Potato flakes, potato granules, and other convenience potato products are restoring potatoes to the important place they once had in the American diet. The per capita consumption of potatoes had been on a downward trend for 50 years, but in the past few years has begun to climb again, and there seems little question that the phenomenal growth of processed potato products has been largely responsible—to the benefit of American potato growers.

A new and promising field of food dehydration now developing involves a technique called "explosion puffing" (*6*). Pieces of potato, carrot, beet, turnip, sweet potato, and apple can be prepared by this process. Conventional dehydration processes can also prepare foods like these, but dehydration is slow and 20 min to a half hour is required for cooking. Eastern Division engineers call the new product "quick-cooking dehydrated fruit and vegetable pieces," because they are ready to eat after 2–6 min simmering, depending on the product. These products are prepared by first partly dehydrating the pieces, then "exploding" them in a low-pressure chamber. The object is not to expand the pieces in size, but to put tiny channels in them by flashing off water vapor. When the pieces are returned to the drier, the rest of the water, which otherwise could be removed only by expensive and time-consuming methods, comes out quickly through these channels. When these dehydrated pieces are cooked, the water readily returns through the same channels. There are immense possibilities for these products. They may make an impact on the food industry such as potato flakes have already made.

The Northeastern and North Central States are especially interested in the paraformaldehyde pellets which were used commercially for the first time last season to disinfect maple tree tapholes (*7*). Years ago basic research on maple sap and sirup at the Eastern Division established the importance of sanitation in sap gathering and sirup production, in order to prevent the spread of quality-destroying microorganisms. Then it was discovered that microbial growth was responsible for the "drying up" of the taphole. Having established the real cause of this loss in the quantity and quality of maple sap, Eastern Division scientists gave the problem of preventing the growth to Michigan State University. The paraformaldehyde pellet developed there, which is simply inserted in the taphole at the beginning of the season, is credited with increasing sap yields by a third to a half in the 1962 season.

Some 30% of utilization research is to basic research. On potatoes, for example, while engineers are working out new dehydration methods, chemists are seeking exact knowledge of the composition of potatoes—knowledge that may provide the key to many processing difficulties that have been encountered. For example an automatic chromatography column is in operation 24 hrs a day, 7 days a week on the problem of amino acid content of potatoes.

Several lines of basic research on animal products, notably on milk and meat, are also being pursued. One study involves casein, the chief protein in milk. Casein is not homogeneous, but consists of at least three individual components, identified as α-, β-, and γ-casein. A calcium-sensitive fraction of α-casein can be identified; it is designated alpha$_s$-casein of milk (*8*) and can consist of three forms, A, B, and C.

Apparently, the genetic inheritance of the cow governs which ones occur in the milk of an individual cow. Since genes occur in pairs, a cow may yield one of six kinds of alpha$_s$-casein: alpha$_s$-AA, -AB, -AC, -BB, -BC, or -CC. This complexity of casein seems to be typical of other milk products as well. Figure 2 shows Dr. M. P. Thompson using the technique of zone electrolysis. This important experimental technique was responsible for revealing the genetic variation of casein.

Figure 2. Zonal electrophoresis of milk proteins in starch gel.

Basic studies on meat have revealed that not all microbial lipases behave similarly toward meat fats. Thus at 35°C *Staphylococcus* lipase releases saturated C_{16} acids from lard much more rapidly than *Pseudomonas* or *Geotrichum* lipase. The low activity of *Pseudomonas* is apparently due to its low ability to attack the 2-position in the glyceride, whereas that of *Geotrichum* is apparently due to low ability to attack saturated fatty acids (*9*).

Leather is another product on which an active program of utilization research is maintained. Synthetic substitutes have cut deeply into the market for leather and threaten to cut still deeper. New methods of preparing hides for tannage and new tanning materials may lower the price and improve the usefulness.

Two promising new tanning materials have been found. One is dialdehyde starch which is especially attractive because scientists at the Northern Division devised a practical way of making it from corn. Using dialdehyde starch as a pretanning agent, fine sole leather can be made in a week, whereas normal sole leather tanning takes six times that long (*10*).

The other new tanning material is glutaraldehyde, which produces soft leather resistant to a variety of agents that deteriorate ordinary leather (*11*). Glutaraldehyde is already in use by some tanners to make high quality garment leathers from sheepskins and shoe upper leathers from cattle hides.

The Southern Division is probably best known for its research on cotton and deserves a lot of credit for the remarkable comeback this versatile fiber has made in recent years in competition with the synthetic fibers. Southern Division scientists have now invented stretch cotton (*12*). Once at a disadvantage because of its lack of elasticity, cotton can now be made into yarns with plenty of stretch and fabrics with plenty of give. It is not hard to imagine the vast new fields for cotton.

While the New Orleans group is carving out new markets for cotton, utilization research scientists at the Western Division in Albany, Cal., have devised a way of overcoming a serious limitation of another excellent fiber, wool. This is shrinkproofing treatment that employs interfacial polymerization (*13*); it is called the Wurlan treatment (Fig. 3). A diamine (A) dissolved in water and a diacyl chloride (B) dissolved in a solvent that does not mix with water interact rapidly at room temperature at the interface between the two liquid solutions to form a colorless polymer film.

Figure 3. Principle of Wurlan treatment.

Continuous treatment of wool fabrics is accomplished by passing the fabric successively through the two solutions. Squeeze rolls remove excess liquid. After treatment the fabric is simply washed and dried. The ultra-thin polymer film is permanently anchored to the wool fibers and gives durable shrink resistance to machine laundering. A treated piece is practically identical in appearance, dimension, and feel to an unwashed piece, even after four 75-min washings. One 75-min washing badly shrinks an untreated sample.

The scientists at the Northern Division have found uses for surplus grains other than dialdehyde starch. An example is kraft paper containing up to 45% cereal starch xanthide or cereal flour xanthide, used as an additive with unbleached kraft wood pulp. It has up to nine times the wet strength and nearly three times the endurance of ordinary kraft paper (*14*). Moreover, the wet strength may be considered permanent, since it is not significantly changed when the paper is soaked for 24 hrs. Preparation of cereal pulps by a xanthation process followed by cross-linking has made possible the first use of grains as an integral part of paper. If this development opens up the vast paper industry as a market for grains, it will be an important contribution to our agricultural economy.

An Inverted Mirror Image

An interesting puzzle can be presented by printing near the top of a blank card in red letters

CHECKED OK

while printing near the bottom of the card

NOT RIGHT

in blue letters.

A glass stirring rod (*not* glass tubing) is placed over the red printing and raised slightly so the printing may be viewed conveniently. Under these circumstances, the printing comes though without apparent distortion. When the blue printing is viewed in a similar manner, the printing appears quite garbled. Incorrect but ingenious explanations are given by the uninitiated to explain this effect. One such explanation is that the effect results from the difference in the wavelengths for the two separate colors. The correct explanation is that the glass rod transmits the original image in the form of an inverted mirror image. The inverted mirror image of only a few letters appears undistorted. These letters are all symmetrical about a horizontal axis.

BOOK REVIEWS

Advances in Heterocyclic Chemistry. Volume 1

Edited by *A. R. Katritzky*, University Chemical Laboratory, Cambridge, England. Academic Press, Inc., New York, 1963. xi + 476 pp. Figs. and tables. 16 × 23.5 cm. $15.

The conventional, comprehensive surveys of heterocyclic chemistry, such as the Elderfield (Wiley) and Weissberger (Interscience) series, are prepared (perhaps among others) under two inherent handicaps. First, there is a considerable time lag between the publication of the first volume of a series and that of the last. By the time the series is complete (if ever), the early volumes are sadly out of date. Second, in order to follow the usual, desirable organization by type of heterocycle and to maintain an economical size, the intercomparison of different heterocyclic series is rather minimal. The present new series of "Advances" promises to correct, at least in part, both of these deficiencies. The series contains both review articles bringing up to date the earlier Elderfield or Weissberger surveys and articles of a comparative nature cutting across whole classes of heterocyclic compounds. Although this approach is not new in isolated reviews, its systematic application promises to be of considerable value in the increasingly difficult struggle of the organic chemist to keep up with the developments in this broad and complex field.

In the present volume are two chapters bringing up to date earlier reviews: Recent Advances in the Chemistry of Thiophenes by S. Gronowitz and Quinazolines by W. L. F. Armarego. Also of a general review nature but encompassing several heterocyclic types is the chapter, Aza Analogs of Pyrimidine and Purine Bases of Nucleic Acids by J. Gut. The remaining chapters survey reactions or structural characteristics common to several heterocyclic series and include: Reactions of Acetylenecarboxylic Acids and Their Esters with Nitrogen-Containing Heterocyclic Compounds by R. M. Acheson, Heterocyclic Pseudo Bases by D. Beke, and two chapters on Prototropic Tautomerism of Heteroaromatic Compounds by Editor A. R. Katritzky and J. M. Lagowski. Written by authorities in their respective subfields who have contributed heavily to recent developments in heterocyclic chemistry, these chapters constitute an admirable selection of topics of considerable current interest not only to heterocyclic chemists but also to organic chemists in general. The chapters by Gronowitz and by Katritzky and Lagowski (and to only a slightly lesser extent the other chapters) illustrate very well the application of physical organic methods to heterocyclic chemistry and should be of interest to all organic chemists. Indeed, all of the chapters are characterized by a fresh, contemporary approach not always found in heterocyclic work.

The selection of topics for the volume is sufficiently clever as to cause one to wonder whether or not subsequent volumes can continue to present reviews of like interest. This question is answered in part by inclusion of a list of the contents of Volume 2, where, on the whole, the continuation of the high level of Volume 1 appears to be reasonably well assured by the stature of the contributors and the selection of topics.

One may argue, of course, that there is no positive assurance that a review by an expert in the field will necessarily be better than one by an abler author of lesser technical achievements. Furthermore, as articles in heterocyclic chemistry become less descriptive and more interpretative in nature, as is the present trend, there may be a tendency for the expert to present *his* interpretation and to depreciate the results or interpretations of others. Happily, the present volume seems to be essentially free of biased interpretations, and only rarely does the choice of examples or data and the evaluation of the results of other workers appear to be somewhat more subjective than objective. Furthermore, the reviews are well written, apparently aimed at a level intermediate between that of the rank novice and the expert in the field. The text is well organized for the reading of an entire chapter or the selective sampling for information on specific topics. This reviewer found no significant errors (except for a few of the inevitable typographical sort). The coverage of the various topics is extensive but not exhaustive. Thus, the reviews will serve as excellent introductions to or points of departure for the intensive study of a given area but not as substitutes for the reading of the original literature.

For many libraries (as well as individuals) the decision as to which, if any, books in a specialized field should be purchased with limited funds is a difficult one. To this reviewer it appears that no organic chemistry library of any but the most fragmentary sort can be assembled without at least one of the basic heterocyclic series (most of the experts in the field prefer the generally excellent and authoritative Weissberger series) and this new series of Advances. Certainly all chemists working in the heterocyclic field will require access to this series and organic chemists in other specialties will find much of general interest here.

College Chemistry

G. Brooks King, Washington State University, Pullman, and *William E. Caldwell*, Oregon State University, Corvallis. 4th ed. American Book Co., New York, 1963. viii + 637 pp. Figs. and tables. 16 × 24 cm. $7.25.

Those who liked the third edition of this well-known text will also like the fourth edition. There are no radical changes, but some improvements and additions. Atomic weights are now based on Carbon-12, a change—as the authors note (p 25)—"not particularly significant for beginning

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

chemistry students." Some of the chapters have been rearranged and new material is presented on chemical bonding, complex ion formation, coordination compounds, bond orientation and bond types. There is no reference to thermodynamic terms such as entropy, enthalpy or free energy. A chapter on transition elements has been added. The type has been reset, and some of the figures redrawn with some improvement in the appearance of the book. Perhaps a third of the exercises in the third edition have been replaced with new ones. A Bibliography replaces the References of the former edition.

Swarthmore College
Swarthmore, Pa.

Handbook of Analytical Chemistry

Louis Meites, Polytechnic Institute of Brooklyn, New York. McGraw-Hill Book Co., Inc., New York, 1963. xv + 1806 pp. Tables. 16 × 23.5 cm. $47.50.

It is not often that a new book represents a substantial achievement in the field of chemistry. The compilation of the "Handbood of Analytical Chemistry" by Louis Meites, however, is truly one of outstanding efforts in the recent years. This new work has some features in common with the handbooks of chemistry and physics that have been published for some time. However, this, new *analytical* handbook has the unique advantage of containing short discussions of the material in each table of data. Inclusion of references and features such as the precision of different analytical determinations makes this book extremely valuable to the practicing analyst.

One is hard pressed to find any topic of analytical importance omitted. Illustration of the scope of the reference may be seen in the treatment of topics such as the analyses of elastomers, pesticides, fertilizers, paints, pharmaceuticals, plastic and resin soaps, water and sewage. This section designated "applied" analysis also has a thorough referencing of the conventionally treated subjects such as coals, mineral petroleum products and alloys.

The extent of coverage, however, varies greatly from one topic to another. This is illustrated by the fact that the portion dealing with fundamental analysis has extremely large and complete sections on functional group analysis, chelometric titrations and polarography. Topics such as conductometric titrations and chronopotentiometry constitute a minor but adequate portion.

This reviewer feels that Professor Meites has consolidated a library-full of references to analytical and physical data into a well-indexed and referenced volume. The one-hundred and thirty authors, including Professor Meites, who himself wrote a substantial portion of the book, deserve special recognition for a difficult job well done. The price, $47.50, may cause many to pause before deciding whether or not to buy this book. (And unfortunately the binding is not of a quality commensurate with the price.) I feel, however, that no chemistry library or laboratory can afford to be without this outstanding handbook.

THEODORE R. WILLIAMS

Wooster, Ohio

Standard Methods of Chemical Analysis. Volumes 2A and 2B, Industrial and Natural Products and Noninstrumental Methods

Edited by *Frank J. Welcher*, Indiana University, Bloomington. 6th ed. D. Van Nostrand Co., Inc., Princeton, New Jersey, 1963. 2613 pp. Figs. and tables. 16 × 23.5 cm. $25 each (not sold separately).

Volume 2 is divided into Parts A and B, bound separately. Part I of Part A comprises a new section of some 500 pages on apparatus, general operations, and reagents. Among chapters not included in the previous edition are qualitative analysis, separations (precipitation, extraction, chromatography, ion exchange, etc.), use of the microscope, quantitative microchemical analysis, and quantitative organic analysis. With the exception of the chapters on detection of cations and anions and on precipitation by change of hydrogen ion concentration, which are quite out of date, the new chapters are much more extensive and up to date than the older chapters. Altogether, the treatment of general topics in Part I of Part A is useful, but analytical chemists in general will prefer to consult more comprehensive accounts, such as monographs, that they already are likely to have at hand.

Part II deals with the analysis of industrial products and special samples, including, among others, air pollutants, alloys, bituminous materials, cement and coal. There is a section on chemical analysis in clinical medicine. Methods of analysis of industrial materials are continued in Part B, with chapters on explosives, fats, fertilizers, paint, paper, pesticides, petroleum, plastics, rubber, silicates, soap, soils, vitamins, water, and other materials. Some of these chapters are new and others have been enlarged to include analytical advances in the quarter century which has elapsed since the 5th edition was published. A number of chapters do not offer adequate literature references, several of the new chapters are much more satisfactory in this respect and also, in general, are more up to date than the older ones. Few modern physicochemical methods of analysis are described.

In spite of these limitations, anyone confronted with analysis of commercial materials will wish to consult this work and, more likely than not, follow its procedures. The strong feature of "Standard Methods" has been, and is, its explicit and detailed presentation of information for the analyst. The whole work is directed to the practical, technical analyst.

Electrochemical Reactions: The Electrochemical Methods of Analysis

G. Charlot, Faculté des Sciences, Paris, *J. Badoz-Lambling*, Centre National de la Recherche Scientifique, Paris, and *B. Trémillon*, École de Physique et de Chimie Industrielles, Paris. American Elsevier Publishing Co., New York, 1963. ix + 376 pp. Figs. and tables. 17.5 × 24 cm. $15.

This text is a translation of a section of the French text "Les Méthodes de la Chimie Analytique." Charlot has written several books on specialized subjects and then combined them into a larger work. In 1959 he published his text "Les Électrochimiques," which was well documented to include references up to 1958. This work was combined with references on spectra and the analysis of elements to yield a large work, "Les Méthodes de la Chimie Analytique," which was published in 1961. The translation was made without any updating of the 1959 text.

The approach used is to introduce general concepts of electrochemistry, making great use of current-voltage diagrams and then attempting to show the relationship of this material to the various specialized areas of electrochemistry. The material is treated in a classical, much less rigorous manner than Delahay's "Modern Methods of Electrochemistry."

There are sections dealing with topics such as non-aqueous solvents, chronopotentiometry, the relationship between amperometry and potentiometry. The sections are very well referenced. Applications of electrochemistry are not treated in great detail.

This should be quite useful to teachers and may be suitable for use at the first year graduate school level. This text merits the attention of those persons interested in electrochemistry.

THEODORE R. WILLIAMS
College of Wooster
Wooster, Ohio

Electrochemistry: Theoretical Principles and Practical Applications

Edited by *Giulio Milazzo*, Instituto Superiore di Sanità, Rome. Translated by *P. J. Mill*. American Elsevier Publishing Co., Inc., New York, 1963. xv + 708 pp. Figs. and tables. 15.5 × 23 cm. $20.

Despite the substantial increase in interest in electrochemistry as a whole throughout the United States, very few textbooks on electrochemistry have appeared in English during the past 10 years. The English revised edition of Professor Giulio Milazzo's textbook which appeared earlier in Italian and German editions is particularly welcome at this time.

The first six chapters of the book are concerned with the more fundamental aspects of electrochemistry. The first chapter presents a concise summary of thermodynamics with emphasis on those aspects which are important to the subsequent applications of thermodynamics to electrochemistry. Electrolytes and elec-

NEW AP BOOKS

High Pressure Physics and Chemistry

Edited by R. S. BRADLEY
Volume 1, October 1963, 458 pp., $15.50
Volume 2, October 1963, 375 pp., $12.50

This treatise provides a comprehensive and advanced study of high pressure science, including both theoretical and experimental work on the production and measurement of static and dynamic high pressures. The gaseous, liquid, and solid states are considered in detail, together with discussions on equations of state, phase equilibria, and transport properties.

The Enzymes

Edited by PAUL D. BOYER, HENRY LARDY, and KARL MYRBÄCK
Volume 8, October 1963, about 475 pp., approx. $16.00
* Subscription price, about $13.60

Volume 8 includes coverage of various porphyrin enzymes, of other oxidases, and of direct oxygenation. The multiplicity of function of the porphyrin structure, as exemplified by enzymes discussed in this volume, is one of the many remarkable features of enzymology.

Diuretics
Chemistry and Pharmacology

By GEORGE deSTEVENS
Fall 1963, about 175 pp., approx. $6.50

The initial chapter of this book is concerned with the physiology of the kidney and the pharmacological methods by which substances are evaluated for their diuretic effects. It sets the stage for subsequent chapters dealing with the chemistry of these compounds and their structure-activity relationships.

Comparative Biochemistry

A Comprehensive Treatise
Edited by MARCEL FLORKIN and HOWARD S. MASON
Volume 6, September 1963, about 475 pp., $20.00
* Subscription price, $18.00

Volume 6 is devoted to chemical views on a number of biological concepts, all of them concerning the level of the complex architecture of cells and organisms.

Newer Methods of Preparative Organic Chemistry

Edited by WILHELM FOERST
Volume 2 translated by F. K. Kirchner
1963, 417 pp., $14.50
Volume 3 translated by Henry Birnbaum
Fall 1963, about 550 pp., approx. $19.00

This work provides a comprehensive survey of the latest developments in selected areas of preparative organic chemistry, filling the need for reviews and summarizations of the work done and suggesting those areas in which more intensive work is needed. References to the original literature and numerous tables are provided.

Metabolic Inhibitors

A Comprehensive Treatise in Two Volumes
Edited by R. H. HOCHSTER and J. H. QUASTEL
Volume 2, Fall 1963, about 675 pp., approx. $26.00
* Subscription price $22.00

The treatise stresses the results of research which shed new light on many biological processes and yield steadily increasing practical applications in such fields as medicine, pharmacology, and agriculture.

On the Primary Processes in Photosynthesis

Physical and Photochemical Aspects, Including a Short Guide to Systematics
By MARTIN D. KAMEN
Volume 1: Part A of Advanced Biochemistry: *A Series of Monographs*
Edited by ANTHONY SAN PIETRO
Fall 1963, about 200 pp., approx. $5.50

This unique work explains the rationales of modern researches into the primary processes of photosynthesis which terminate before the onset of biochemical and physiological phases. The bases of physical and photochemical investigations on the photosynthetic apparatus are presented and illustrated by examples from recent literature.

Chemical Applications of Infrared Spectroscopy

By C. N. R. RAO
Fall 1963, about 625 pp., approx. $20.00

This new book, on one of the most powerful techniques available for chemical analysis, presents the basic concepts, measurements, and techniques of infrared spectroscopy.

Modern Polarographic Methods

by HELMUT SCHMIDT and MARK VON STACKELBERG
Translated from the German by R. E. W. Maddison
1963, 99 pp., $5.50

Recent developments in polarography, a specialized branch of electro-chemistry, are summarized and reviewed in this new work. The advantages and disadvantages of new procedures, as well as their significance for chemical analysis and the resolution of scientific problems, provide a working theme.

Ultracentrifugal Analysis in Theory and Experiment

Proceedings of a Conference Sponsored by the National Academy of Sciences
Edited by J. W. WILLIAMS
1963, 282 pp., $10.00

Concentrating on three basic areas, transport theory, sedimentation equilibrium theory, and actual practice, twenty experts in the subject examine the efforts to solve the outstanding mathematical and operational problems inherent in ultracentrifugal analysis, and the possible use of the ultracentrifuge in biological and medical research.

Microscopic Characters of Artificial Inorganic Solid Substances

Third Edition
By ALEXANDER NEWTON WINCHELL and HORACE WINCHELL
Fall 1963, approx. 325 pp.

The book presents available data on and a graphic summary of the optical properties of inorganic solids, and a reference to readily available X-ray Powder Data of the substances described.

** Subscription price valid on orders for the complete set received before publication of the last volume.*

Detailed information available upon request.

WILEY BOOKS

CHEMISTRY

A Survey of Principles

By GALEN W. EWING *and* E. GERALD MEYER, *Professors of Chemistry, New Mexico Highlands University.*

This book presents the fundamental principles of chemistry by selecting representative concepts, systems, substances, and reactions from present-day chemistry and treating them in depth. It develops the basic theory and provides a general description of such important topics as biochemistry, organic reaction mechanisms, thermodynamics, chemical equilibrium and reactions, and metal-organic and metal-inorganic complexes. The interaction between theory and experiment is emphasized consistently.

Special Features:

- The book's cross-section of present-day chemistry includes not only basic concepts and methods, but also excursions into fascinating research at the frontier of knowledge
- Laboratory experiments are an integral part of the book: Most of them are quantitative in nature, and many develop concepts not treated in the text or employ such modern laboratory instruments as the *pH*-meter, photoelectric colorimeter, and nuclear counting equipment
- A selection of portraits is included, giving thumbnail biographical sketches of scientists who led in the development of chemistry
- Review questions, including "think" and "black box" as well as straight numerical problems, appear at the end of each chapter

This text is designed for one-semester chemistry courses for non-majors, and has high-school algebra as its *only* prerequisite. *1963. 239 pages. $4.95.*

PHYSICAL ORGANIC CHEMISTRY

By KENNETH B. WIBERG, *Professor of Chemistry, Yale University.*

The trend in most books on physical organic chemistry has been to stress the organic *chemical* aspects of the subject. This new text, however, concentrates more on the *physical* chemical aspects—and emphasizes the application of the methods of physical chemistry to the study of organic chemical phenomena. *Physical Organic Chemistry* is divided into three parts: Bonding and Spectra—Equilibria—Kinetics. These are given far more complete coverage than that offered by comparable texts. Throughout the book, specific examples are introduced that show how the material presented may be applied to the study of organic compounds. The highly useful appendix contains a review of matrix algebra, tables of constants and other numerical data, and additional important, related information. It features a discussion of computer programming—an area increasingly important to organic chemists. *1963. Approx. 600 pages. Prob. $10.75.*

Send for examination copies.

THIN-LAYER ELECTROPHORESIS

Two-dimensional separation of 5 amino acids on silica gel, first by electrophoresis, then by chromatography: 1. Arginine 2. Glutamic acid 3. Valine 4. Histidine 5. Leucine

Thin-layer electrophoresis is a new analytical technique which combines with thin-layer chromatography to give you separations that you can't get by using both techniques separately. Scientists experimenting with TLE report instances of unexpectedly high mobilities as well as greater speed, sharper resolution, increased sensitivity, wider range of sample size, better reproducibility, and other advantages. □ RSCo is the only domestic company which makes complete equipment for TLE, and our dealers now have it in stock. If you already use RSCo electrophoresis or other flatbed equipment, you can adapt it to TLE with our assembly at a cost of only $162.

Want more information? Write for our free RSCo Review, Vol. 5, No. 5.

RESEARCH SPECIALTIES CO.

200 So. Garrard Blvd., Richmond, Calif.

trolytic conductance are treated effectively in the second chapter, although the material presented in this chapter does not go much beyond that found in many of the more complete undergraduate physical chemistry textbooks. The third chapter on galvanic cells provides a reasonably comprehensive discussion of the thermodynamics of electrochemical cells. A well organized introduction to electrochemical kinetics is presented in the fourth chapter although very little information is included on experimental methods for the study of electrochemical kinetics. Chapter 5 is concerned with analytical applications and includes sections on electrolytic analysis, potentiometry, conductance methods, and polarographic and voltammetric methods. Chapter 6 gives a brief introduction to the fundamental aspects of colloid chemistry and then discusses some of the analytical and industrial applications for electrophoresis and electrokinetic phenomena.

With the exception of Chapter 12 on the electrochemistry of gases the remainder of the book is concerned primarily with industrial applications including electrodeposition, electrorefining, industrial electrolysis, batteries, and corrosion. The chapters on the applied aspects of electrochemistry are primarily descriptive but not excessively technological in nature. In most instances only a broad survey of the field of application is presented.

Four of the twelve chapters in this text are co-authored by other European electrochemists. Continuity, however, has been preserved between all of the chapters. The book as a whole is well organized and the presentation of complex ideas and concepts quite easy to follow. Dr. P. J. Mill who translated this new English edition from the Italian manuscript is to be commended for his translation.

Particular features of the book which are noteworthy are its numerous tables of data based on recent literature and the list of symbols and their definitions which appear in the beginning of the book.

This book is intended primarily to serve the function of a teaching textbook and is suitable for an upper undergraduate or beginning graduate level course in electrochemistry. An undergraduate course in physical chemistry emphasizing thermodynamics is a prerequisite. Since very few courses in electrochemistry are offered at any level in colleges and universities in the U.S. it is questionable whether the book will find wide use as a textbook for college courses in this country. Furthermore, no problems are provided in the book. For physical chemistry courses at both the undergraduate and graduate however, this book represents worthwhile collateral reading.

The recommendations of the IUPAC nomenclature commission are followed throughout the book relative to sign conventions as well as nomenclature. This may cause students using the book for collateral reading in courses in physical chemistry some difficulty, since the physical chemistry textbooks in this country generally have not adopted the IUPAC recommendations on nomenclature in the

(*Continued on page A823*)

What's your best buy in Beakers?

PYREX® brand beaker No. 1002—for two good reasons: it's stronger, and more versatile. An improved rim and spout plus tighter tolerances on wall thickness and radii make it stronger. Approximate graduations add utility. Now at the same low price as our plain No. 1000 beakers.

Try it. See if you don't agree the 1002 is your best buy in beakers.

You'll find *all* the best buys in the new, blue PYREX brand labware Catalog LG-3. If you don't have a copy, write Laboratory Glassware Dept., 7710 Crystal St., Corning, N. Y.

NEW AND FORTHCOMING TEXTS FROM McGRAW-HILL

☐ ORGANIC CHEMISTRY, Second Edition

By DONALD J. CRAM, University of California, Los Angeles; and GEORGE S. HAMMOND, California Institute of Technology. Available in January.

This excellent revision continues to stress the principles that govern organic reactions rather than relying on mere description. The first part acquaints the reader with structural concepts, the middle part with organic reactions taken up class by class, and the last part includes a more conventional treatment of special topics. The approach stresses understanding rather than memorization. The new edition has been expanded and presented in a more desirable sequence. In addition, the book has been printed in two colors . . . the second color being used chiefly to distinguish the active chemical groups in the reactions. This will make it far easier for the student to follow the complex changes that take place in complicated organic reactions.

☐ ORGANIC CHEMISTRY, Second Edition

By CORWIN HANSCH, Pomona College, and GEORGE HELMKAMP, University of California at Riverside. Off press.

As in the first edition, the text presents a very concise outline of organic chemistry, but its primary purpose is to provide a large number of problems and specific help in learning to solve these problems. Each chapter begins with simple questions and answers which lead gradually to more difficult problems, thus reinforcing the student's desire to learn each time he perceives he has answered a question correctly. A new chapter on molecular orbitals has been included, and the mechanisms of organic reactions are emphasized more than in the first edition.

☐ EXPERIMENTAL GENERAL CHEMISTRY WITH PROBLEMS

By JAMES D. McCULLOUGH, University of California at Los Angeles; and HOSMER W. STONE, Emeritus Professor of Chemistry, U.C.L.A. 320 pages, $3.50.

In this new revision of the authors' *Experiments, Theory, and Problems in General Chemistry*, the material has been completely rewritten and theoretical discussions have been condensed among the introductory paragraphs of various assignments. The quantitative approach is emphasized, as are the application of principles and logic to problems rather than rote memorization. Among the 33 laboratory assignments given four new assignments are provided. The experiments range from simple to quite difficult. Safety is stressed throughout the manual and an Instructor's Manual will be available.

☐ GENERAL CHEMISTRY LABORATORY STUDIES AND PROBLEMS: With Tear-Out Reports

By HOSMER W. STONE and JAMES D. McCULLOUGH. Off press.

This version includes tear-out data and report forms. In both editions the student is instructed on method and then is required to prepare a written report covering required observations and data, required calculations and questions, and problems for further study.

☐ PHYSICAL AND CHEMICAL METHODS OF SEPARATION

By EUGENE W. BERG, Louisiana State University, Baton Rouge. 384 pages, $12.50.

For the first time in a single volume, this text presents eighteen laboratory separation techniques. The author's aim is to enable the advanced student to recognize the inherent limitations of these separation methods and the type of system to which each method would be applicable. Emphasis is on the physical principles which govern the behavior of a given method. An effort is made to pinpoint the important system variables, with a minimum of mathematical detail. Experimental detail is avoided through the use of schematic diagrams of the needed equipment, with brief descriptions of the technique.

☐ ENTROPY

By J. D. FAST, Chief Metallurgist Philips Research Laboratories and Professor at the Technical University of Eindoven. In press. 313 pages, $10.75.

This book has been prepared in order to develop and elucidate the significance of the concept and its applications in science and technology in a manner clear enough to be readily understood by physicists, chemists, and students. The author presents basic, necessary principles of thermodynamics, statistical mechanics and quantum mechanics in such a manner that the non-theoretician can profit from an understanding of the valuable entropy concept. This treatment of entropy was so successful in an earlier Dutch edition that the present volume is being simultaneously published in Dutch, English, French, German, Spanish and Polish.

☐ INTRODUCTION TO BIOPHYSICAL CHEMISTRY

By R. BRUCE MARTIN, University of Virginia. Modern Biology Series. Available in January.

This new text covers the application of fundamental principles to small molecules of biological significance, covering the methods for characterizing biopolymers and a study of their properties and interrelationships. Among the topics: the thermodynamic basis of biological reactions, a systematic presentation of acid-base equilibria, and the properties, functions, and interrelationships of biologically important macromolecules, proteins, and nucleic acids.

☐ CHEMICAL ENGINEERS' HANDBOOK, Fourth Edition

Edited by ROBERT H. PERRY, Middle East Technical University; CECIL H. CHILTON, and SIDNEY D. KIRKPATRICK. McGraw-Hill Series in Chemical Engineering. 1900 pages, $23.00.

Through the efforts of the three chief editors, 26 section editors, and 109 contributors, the fourth edition of this classic reference work for the chemical engineer has been modernized and reorganized to reflect the close interrelationships of chemical principles with operating practice. This emphasis upon fundamentals makes the book applicable to specific problems in such rapidly developing fields as missiles and nucleonics, where a "hardware"-oriented approach would be obsolete on publication. The book retains the comprehensive character and broad, authoritative coverage that characterized it when it was devoted to a younger, narrower subject area. The essential concern with costs remains, and the reader will find guidance on selecting economic pipe diameters, financial tables, charts of unit costs for various types of plant facilities, profitability studies, and forms for working out return-on-investment calculations.

PRENTICE-HALL CHEMISTRY TEXTS

ELECTRONIC SPECTRA and QUANTUM CHEMISTRY

by C. Sandorfy, *University of Montreal*

Here is an easy-to-read introduction to research in electronic spectra, emphasizing the larger molecules of interest to chemists. Its main subject is the description of approximate wave mechanical methods, making it possible to compute theoretically the frequencies and intensities of spectral bands. The book provides a *working knowledge* of quantum chemistry and spectroscopy. *Feb. 1964, approx. 352 pp., Text pr: $10.00*

FUNDAMENTALS OF GENERAL CHEMISTRY, 2nd Ed.

by C. H. Sorum, *University of Wisconsin*

The fundamental principles of general chemistry are concisely presented at a level that will challenge the good student and lay a firm foundation for future courses in analytical, organic, and physical chemistry. The treatment of the material is quantitative and the entire text is supported by a generous collection of thought-provoking questions and problems. *May 1963, 707 pp., Text pr: $8.50*

SELECTED PRINCIPLES OF CHEMISTRY

by Jay A. Young, *Kings College, Pa.*

Intended as an adjunct to any standard introductory chemistry text, this book increases the student's understanding of the subject matter. It treats those topics in elementary chemistry which are either very difficult, important, or both. The approach is by programed instruction which helps the student to learn by presenting the material in an ordered manner, and by requiring his participation and written responses. *August 1963, 161 pp., paperbound Text pr: $2.95*

COLLEGE CHEMISTRY, 3rd Ed.

by Paul R. Frey, *Colorado State University*

This new 3rd Edition has been revised throughout. In particular, the approach to atomic structure is changed. Greater stress is placed on probability of electron position (electron clouds), ionization potentials, electronegativities, and bond energies. A number of charts and figures have been added to show the meaning of these concepts. Many new exercises and problems are included. *April 1964, approx. 800 pp. Price to be announced*

fields of thermodynamics or electrochemistry.

ERNEST YEAGER
Western Reserve University
Cleveland, Ohio

Textbook of Organic Chemistry

Alexander Gero, Hahnemann Medical College, Philadelphia. John Wiley and Sons, Inc., New York, 1963. ix + 679 pp. Figs. and tables. 17.5 × 24.5 cm. $0000

Recent years have seen the inclusion of increasing amounts of material on reaction mechanisms in the elementary organic chemistry course, a trend with which this reviewer is wholeheartedly in favor. At least two excellent texts stressing this approach—Cram and Hammond, and Morrison and Boyd—have already appeared. Another—Roberts and Caserio—is waiting in the wings. Judged in such company, the present volume, which also attempts a modern approach to organic chemistry, comes off rather poorly indeed. In fact much of its presentation of "mechanisms" will give a physical-organic chemist pause.

First of all, except for isolated spots, the book generally ignores the most basic premise of all mechanistic considerations relative to the effect of structure on reactivity, namely, that the rate of an organic reaction is determined by the energy (or more accurately, free energy) difference between reactants and transition state. Instead it chooses to attempt to explain structure-rate effects almost entirely on the basis of differences in ground state energies of reactants, a procedure which is theoretically incorrect, and despite the fact it often leads fortuitously to correct predictions, is pedagogically indefensible, particularly in the elementary course, which represents the critical formative period of a student's basic approach to organic chemistry.

Second, the following peculiar statement relative to the canonical forms of a resonance hybrid occurs on p. 64: "The course of its [a compound's] reactions, however, may be determined more by the higher-energy canonical structures because the principal structure with its lower energy is less likely to be responsible for change than the more unstable, higher-energy canonical structures." This extremely questionable statement then proceeds to attain the status of a first principle and is employed repeatedly in the remainder of the book, as the supposed mechanistic explanation for various phenomena.

Some typical examples of the types of errors that occur throughout the book and that detract seriously from its treatment of reaction mechanisms are: On p. 81 in discussing the acidity of cyclopentadiene the statement is made that the cyclopentadienyl anion is more stable than cyclopentadiene. If this were literally true cyclopentadiene would have a K_a greater than unity, which, of course is not true. On p. 106 there occurs an obviously incor-

What's your best buy in heavy duty beakers?

Months of field tests in 25 major laboratories *prove* that it's the new PYREX® brand Heavy Duty Beaker.

It outlasted conventional types by 3 to 5 times in the field tests, cutting replacement costs up to 40%. In our own tests—in a special machine that bangs beakers together hard, bumps them down hard—it has outlasted all other Griffin types by as much as 20 to 1.

The No. 1003 Heavy Duty Beaker will give you superior performance in your toughest lab jobs because we make it with a new process that yields extra-heavy rims and extremely uniform walls.

Test it in your own lab. See how much you can save on replacements. Order now through your labware dealer.

Want more information? Write Laboratory Glassware Dept., Corning Glass Works, 7710 Crystal St., Corning, N. Y. And ask for the new, blue PYREX brand Labware Catalog LG-3 if you don't yet have a copy—it has *all* the *best buys* in labware.

VALUABLE · NEW BOOKS FROM MACMILLAN

BIOGENESIS OF NATURAL COMPOUNDS: A Review

Edited by *P. Bernfeld,* Bio-Research Institute, Inc., Cambridge, Massachusetts

A thorough review of current knowledge and research in the field of natural compounds. The first section deals with compounds occurring in both the animal and the vegetable kingdoms, and the second covers substances synthesized only by plants or microorganisms.

Partial contents:

The Biosynthesis of Amino Acids—*James R. Mattoon;* The Biosynthesis of Steroids—*Ezra Staple;* The Biogenesis of Proteins—*Kivie Moldave;* The Biogenesis of Conjugation and Detoxication Products—*R. T. Williams;* The Biosynthesis of Phenolic Plant Products—*T. A. Geissman;* Alkaloid Biogenesis—*Edward Leete;* The Biosynthesis of Fungal Metabolites—*W. Basil Whalley.*

A Pergamon Press Book *1200 pages, $28.00*

SOLUBILITIES OF INORGANIC AND ORGANIC COMPOUNDS, Volume 1, Binary Systems (In two parts)

Edited by *Professor H. Stephen* and *Dr. T. Stephen,* Oxford

These are the first volumes of a comprehensive survey of the data published on the solubility of elements and inorganic, metallo-organic, and organic compounds in binary, ternary, and multicomponent systems. The material was obtained from a detailed review of periodical literature in all languages conducted by a panel of scientists appointed for the purpose by the Academy of Sciences of the U.S.S.R. The two parts of Volume 1 deal with solubility in water and anhydrous solvents. Information is presented in the form of 6,540 tables, arranged systematically for easy reference. Part 2, now in preparation, will contain both a formula index and an index of compounds.

A Pergamon Press Book *Part 1, 960 pages, $28.50*
Part 2, 1004 pages, $28.50

International Encyclopedia of Physical Chemistry and Chemical Physics, Topic 11, Volume 1:

APPLICATIONS OF NEUTRON DIFFRACTION IN CHEMISTRY

By *G. E. Bacon,* A.E.R.E., Harwell

Designed to show chemists the value of "neutron crystallography"—the study of diffraction patterns of solids and liquids produced by beams of neutrons from nuclear reactors. The book pays particular attention to the study of molecular structure, hydrogen bonds, and thermal motion through the determination of the position of hydrogen atoms.

Chapter headings:

Hydrogen Bonds in Inorganic Compounds; Organic Compounds; Heavy Element Compounds of Carbon, Nitrogen, and Oxygen; Metal Hydrides and Ammonium Compounds; Compounds Which Include Neighboring Elements; Magnetic Materials: An Outline; The Study of Liquids and Gases.

A Pergamon Press Book *156 pages, $5.50*

COSMETIC SCIENCE 1962

Proceedings of the Second Congress of the International Federation of Societies of Cosmetic Chemists, London, 1962 Edited by *A. W. Middleton*

The results of laboratory research and clinical studies from all over the world are reported in these papers. Dermatologists as well as industrial chemists will find important new data in the book.

Partial contents:

The Measurement of Perspiration Insensibilis—*L. Šerák* and *P. Hybásek;* The Sebographical Skin Test—*K. Roth;* The Mechanisms of Allergic Contact Sensitization—*C. D. Calnan;* Dermal Neutralizing Ability—*M. Saitoh* and *M. Inomato;* The Cosmetological Application of Lysozyme Chloride—*G. Vandoni, P. Rovesti,* and *M. Arbasino;* An *in vivo* Assessment of fluoride Toothpaste—*A. W. Holmes;* The Removal of Radioisotope Contamination from Surfaces—*D. G. Stevenson.*

A Pergamon Press Book *270 pages, $12.50*

ELEMENTARY INFRARED SPECTROSCOPY

By *Clifton H. Meloan,* Kansas State University

A non-mathematical presentation for those with no previous background in spectroscopy, this book offers a concise analysis of the capabilities and limitations of infrared instrumentation. Professor Meloan provides a brief history of the process, describes the basic equipment, and acquaints the reader with the standard terminology. He shows where infrared fits into the electromagnetic spectrum and gives examples of the interconversion of units of energy and wavelength. Theories, techniques, and practical applications are illustrated by interpretations of sample spectra.

Approximately 192 pages, $8.95

DIGITAL COMPUTER PROGRAMS FOR PHYSICAL CHEMISTRY, Volumes I and II

By *Paul A. D. deMaine* and *Robert D. Seawright*

This valuable work is an outgrowth of research conducted at the University of Mississippi. It describes an integrated system of individual programs for the rapid and precise processing of information in which the operator preselects limits for the experimental error. Only data describing the mathematical model to within the prescribed limits are used to determine each parameter and its maximum permitted deviation. The method may be used to test whether experimental information is described by any of a series of mathematical models for which programs are available. Both FORTRAN and ALGOL 60 programs are given. Volume II supplies valuable FOR-TO-GO programs for communicating with the IBM 836 Autoplotter.

Volume I, approximately 425 pages, $18.00
Volume II, in preparation

SCHUCO

SEMI-MICRO SETS

for • EDUCATION
• RESEARCH
• INDUSTRY

• Complete, Compact, Ready for Use
• Framework and Supports Included
• Low Cost and Minimum Breakage
• Cabinets Contain all Components

The SCHUCO range of SEMI-MICRO apparatus provides simple, compact sets ideal for school use to sets giving over twenty different assemblies for post-graduates and the research worker. Unique features are the special portable cabinets complete with fittings, including acid resistant working base, rigid metal framework and micro burner. The clamp/bosshead attachments which support the glass apparatus eliminate traditional bossheads and clamps making the whole outfit a composite "ready-to use" apparatus needing no extras.

*Set No. E. S. 7: Consisting of 16 components with ground joints. Complete with cabinet and framework...$69.00

*Set No. E. S. 8: Consisting of 21 components with ground joints. Complete with cabinet and framework...$84.00

*Set No. E. S. 11: Consisting of 6 components which can be used to supplement either set E.S. 7 or E.S. 8. Can also be used as simple introductory set. Complete without case or framework. $13.00

*Quantity Discounts: 1-11 sets net; 12-23 sets 10%; 24-29 sets 15%; 50 or more sets 20%. Sets E.S.7 and E.S. 8 only may be assorted to earn quantity discounts.

Available from SCHUCO or your Lab Dealer.

rect explanation of the mechanism of the disproportionation of alkylbenzenes. On p. 191 it is strongly implied that tertiary alkyl halides do not undergo E2 elimination when in actual fact these halides undergo such eliminations much more readily than secondary or primary halides. On p. 207 in sec. 7.12 and p. 275 in sec. 10.20 occur two of the many (at least 20) examples of the application of the unusual postulate, referred to earlier, about reactions involving the most unstable canonical forms of a resonance hybrid. On p. 274 the failure of most ketones to form bisulfite addition compounds is ascribed to a rate phenomenon rather than to the fact the over-all equilibrium is unfavorable.

A further general criticism of the book's treatment of mechanism is that it gives much too little emphasis to the very considerable role which steric effects play in a wide range of organic reactions.

It is a pity that the treatment of reaction mechanisms comes off so poorly, for the treatment of descriptive organic chemistry is generally good, and the book as a whole is quite readably written. It also has the feature of providing unusually detailed coverage of heterocycles, and quite extensive coverage of other biologically or pharmaceutically important compounds. Treatment of stereochemistry varies from excellent in the chapter dealing with ring strain and geometrical isomerism (Chap. 4) to acceptable in that (Chap. 9) dealing with optical isomerism.

However, because of the shortcomings of the book's treatment of mechanisms and because this material is so extensive, and so interwoven with the rest of the text that it cannot be overlooked or omitted, this reviewer regretfully cannot recommend adoption of Gero's book as an elementary organic text.

JOHN L. KICE
Oregon State University
Corvallis

Semimicro Experiments in Chemistry

John W. Sulcoski, Dallas Senior High School, Dallas, Pennsylvania. Burgess Publishing Co., Minneapolis, 1963. viii + 128 pp. Figs. and tables. 21.5 × 27.5 cm. Paperbound. $2.90.

"Semimicro Experiments in Chemistry" has been written for those chemistry instructors who like the concept that experiments in the student manual should contain no fill-in blanks, but rather should require an essay-type student report. The general format for this report is included in the teacher's manual and, if followed, should ease the problem of grading and improve the laboratory instruction.

There are 51 experiments in the manual, more than half of which are quantitative in scope, requiring measurement, graphing, and interpretation of data. The experiments follow the "open-ended" idea pioneered by the Manufacturing Chemists Association. The directions are brief but sufficient. Questions are posed for good

(*Continued on page A827*)

What's your best buy in Transfer Pipets?

Engaged in research? Then it's the PYREX® brand pipet No. 7100—you just can't get one more accurate.

It's made as rugged as it is accurate to give you long useful life. ACCU-RED™ markings and capacity ring are fired into the glass for permanence.

If you're teaching, your best buy is the PYREX brand pipet No. 7102. They're just as rugged as the 7100, but have larger tip openings to speed experiments. Accuracy tolerances, while twice those of the Class A 7100, are close enough for most student work.

Check *all* the best buys in laboratory glassware. You'll find them in the new, blue PYREX brand labware Catalog LG-3. If you need a copy, write Laboratory Glassware Dept., Corning Glass Works, 7710 Crystal St., Corning, N. Y.

observation. The student report includes a series of essay questions which require careful observation and interpretation of data. It is also suggested that the student report include equations for all the reactions involved.

The experiments are a little more sophisticated than those found in the usual high school laboratory manual. Excellent suggestions are contained in the teacher's manual. These include a general commentary on each experiment, lists of chemicals for each experiment, a quantitative list of chemicals needed for the entire course, apparatus list for the student locker and additional equipment needed in the laboratory. A list of stock solutions and their preparation is also included. There are suggested reference books and a short listing of suppliers for chemicals and equipment.

All the laboratory equipment is pictured. The manual suggests using semimicro equipment for the investigations although this would not be necessary. The introductory experiment on laboratory techniques appears to be very well written and easily followed by the beginner.

The author should be complimented for his effort to improve upon the laboratory instruction in the high school.

Calculations in Physical Chemistry

B. W. V. Hawes and *N. H. Davies.* John Wiley and Sons, Inc., New York, 1962. xiv + 203 pp. Tables. 14 × 21 cm. $4.50.

This little book covers the areas of classical physical chemistry as well as having chapters on Atomic Physics and Nuclear Chemistry and Molecular Structure. Each chapter consists of a series of problems with notes given to guide the student in solving them. The result will give the student practice in the manipulation of chemical calculations but does not serve too well in giving him a better insight into the theory behind the problem, so that he can later tackle the non-standard problems he may face. Answers for all problems are given at the end of the book.

The problems are for the most part fairly straightforward and routine, and do not involve extensive calculations, graphical integrations, etc., which are often encountered in practice. The book was designed to give British students practice for the various examinations that are a part of the British educational system. Many of the problems are actually taken from previous examinations.

Regretably the authors have not recalculated data to conform to the ^{12}C = 12.0000 atomic mass scale. They also have not been consistent in their conventions of cell potentials and use both oxidation and reduction half-cell potentials rather than changing them to conform to recommendations of the Stockholm convention.

This book should serve as a useful source of the type of question which tests whether or not the student has learned the simple basic relationships of physical chemistry. As such it should be valuable to teachers of physical chemistry as a source for examination question ideas or to students as a check to see whether or not they can deal adequately with the straightforward problems.

College of Wooster
Wooster, Ohio

Physicochemical Hydrodynamics

Veniamin G. Levich, Academy of Sciences, USSR. Translated by Scripta Technica, Inc. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1962. xvi + 700 pp. Figs. and tables. 16 × 23.5 cm. $15.

This is the translation into English of the second edition of a book which was first published in the U.S.S.R. in 1952. The translation was prepared by Scripta Technica, Inc. and edited by L. E. Scriven assisted by A. Acrivos, J. Newman, T. J. Hanratty, S. Bruckenstein, and W. E. Ranz. It should prove to be a veritable gold mine of information for chemists and chemical engineers who deal with small scale hydrodynamics including especially the motion of drops, bubbles, and particles in fluid media, wave motion on a liquid surface, and motion in thin films. Although the title of the book stresses hydrodynamics, the other transport phenomena are not neglected. For instance, there are sections on convective diffusion to the surface of a rotating disk, diffusion in the concentration range near a critical solution point, the passage of current through an electrolytic solution, and the effect o surface active agents on the motion of bubbles, drops and waves. Many of these topics are just beginning to attract attention in the United States, and it is quite surprising to find that Professor Levich and his colleagues have been working intensively on such problems for a period of 20 years during which the theory has been developed to the point where an authoritative monograph could be prepared.

The material has been presented in an easily understood manner. Although the development of each topic eventually results in a mathematical analysis, the actual calculations are usually accompanied by a good narrative discussion in which the salient points are clearly presented. Within a given broad area, the author frequently discusses a series of related problems of increasing complexity and physical reality. The methods of higher mathematics are used whenever they are required. However, one never gets the feeling that the author is solving a mathematical exercise as an end in itself. In many cases, appropriate approximations are used in order to reduce the complexity of the analysis. As one would expect, this means that most of the discussions of such phenomena as diffusion to drops and particles are framed within the context of boundary layer theory.

There may be a few advanced under-

(*Continued on page A829*)

What's your best buy in Graduated Cylinders?

For research, it's the PYREX® brand cylinder No. 3050. You can see why—large numerals and fine graduations of fused-in ACCU-RED™ for accuracy, permanence, and strength—a tough shoulder of glass that stays put to prevent tipping chipping—the stable hexagonal base that resists toppling and can't roll.

For teaching, it's the PYREX brand No. 3075 cylinder. Real price economy—detachable plastic hex base—sharp white enamel graduations, large numerals.

These are just two of the best buys in laboratory glassware that you'll find in the *new*, blue PYREX brand labware Catalog LG-3. If you don't have your copy, write Laboratory Glassware Dept., Corning Glass Works, 7710 Crystal St., Corning, N. Y.

graduate students who have progressed to the point where they can profitably study from this book, but it is probably best described as a graduate level text. Since only five and one-half pages are devoted to the continuity equation, the Navier-Stokes equations, and hydrodynamic boundary conditions, study from a book such as "Transport Phenomena" by Bird, Stewart, and Lightfoot would appear to be a prerequisite to effective use of "Physicochemical Hydrodynamics." Roughly the same amount of space is devoted to stating the equations of convective diffusion. Although the book is not suitable as a first text in transport phenomena, at least not without extensive supplementation, there is little doubt that many of the topics discussed in it will find their way into advanced courses.

The book is not a particularly handsome volume. The equations were apparently reproduced from the original Russian edition and, as a result, the symbols used in the text are somewhat different than those used in the equations. Furthermore, too many of the letters are improperly formed; for instance, there are eleven flaws on page five. On first reading, eleven obvious typographical errors were detected in the first sixty pages, but other sections were better.

In summary, "Physicochemical Hydrodynamics" is undoubtedly an important book which will influence thinking and research for many years to come. We are fortunate that it has been translated into English.

Nouveau Traité de Chemie Minérale. Volume 9, Titane, Zirconium, Hafnium, and Thorium

Paul Pascal, general editor. Masson et Cie., Paris, 1963. xxxix + 1211 pp. Figs. and tables. 17.5 × 26 cm. 200NF, broché; 212NF, cartonné toile.

Volume 9 and the eighth volume of Pascal's new treatise on inorganic chemistry are organized to cover the materials concerning elements of Group IV. This volume is devoted to titanium, zirconium, hafnium, and thorium. Chrétian and Freundlich are authors of the section on titanium, Albert, Langeron, and Lehr of that on zirconium and hafnium, and Flahaut is sole author of the section on thorium. About half of the volume is reserved for the material on zirconium and hafnium, and the remainder is about equally divided between titanium and thorium. Much emphasis is placed upon processes for the extraction and purification of the four elements, particularly for those involving zirconium and hafnium.

Much attention has been given to the bibliographies, and there are some 6600

NEW! MALMSTADT-ENKE INSTRUMENTATION LAB... IDEAL FOR RESEARCH & EDUCATION IN CHEMICAL INSTRUMENTATION & CONTROL

Complete Lab Station $1100 (Less optional cabinet)

Completely Factory Assembled & Calibrated, This Coordinated System Is Ready To Use... Available As A Complete Lab Or As Individual Instruments!

Whether you're a professional researcher in physical or life sciences, or an educator who's concerned with the teaching of chemical instrumentation, you'll find this low cost Malmstadt-Enke system ideal for providing a solid foundation in the principles, design, and use of electronic instrumentation. Designed by Dr. H. V. Malmstadt of the University of Illinois and Dr. C. G. Enke of Princeton University and engineered and manufactured by Heath, this highly accurate, highly sensitive equipment meets the industry's top standards in form and function. Therefore, experiments are not performed "by analogy" or with gross simplification, but are typical of the best in modern laboratory practice.

Included in this multi-purpose system are factory assembled and calibrated test equipment, new, special-design instruments, special experimental chassis and parts which feature "solderless" spring clip connectors and conventional component layout, plus the authoritative Malmstadt-Enke text, "Electronics for Scientists".

All of the various components may be purchased either as a complete lab station or individually for specific applications. When purchased as a complete station, these instruments offer additional savings over their individual prices. Educational institutions qualify for an additional discount on the entire group as well as individual units. Export models for 115/230 VAC, 50-60 cps are also available; write for details. For a free 8-page brochure describing this system in detail, plus a complete "low acquisition" price listing, simply mail the coupon below.

Servo-Pen Recorder
Worth five times its cost! True potentiometric input; 5 adjustable ranges, 10, 25, 50, 100 and 250 mv plus plug-in connectors for special ranges and applications; rapid chart advance; pen lift; 10" chart; 1 sec. response. 20 lbs.
EUW-20A $195.00

Operational Amplifier System
Many applications in measurement, computation and control work described in brochure. Self-contained ± 300 V. power supplies, 4 hi-gain, stable, rapid response operational amplifiers, and booster power amplifier. 5-pin connectors. Blank chassis for plug-on circuits available. 18 lbs.
EUW-19A $135.00

Universal Lab Power Supply
Ideal for circuit design or teaching power supply design; provides many different types of power supply circuits with fast, simple wiring changes. Output 200 to 350 VDC, 0-100 ma, regulated to less than 1% variation. Unregulated output, 100 to 500 V in five steps. 15 lbs.
EUW-15 . . . . . $75.00

Voltage Reference Source
Use for calibration, potentiometric measurements, or calibrated bucking voltage. Zener-stabilized, provides ± 1% or 0.1 mv accuracy over range of 0.1 mv to 100 volts. Readout directly on three dials. Coarse and Fine controls. 6 lbs.
EUW-16 . . . . . $65.00

references included in the work. Yet despite a publication date of 1963, with some exception, most of the searching of the literature appears to have been done prior to 1961. Bibliographies for titanium and thorium do not go beyond 1960, and appear to have been prepared primarily in 1958.

Illustrations are employed frequently throughout the volume, as well as numerous tables. Ten pages of indexes are included, but in general the indexes are not especially thorough, although metal systems are well indexed. This is helpful in locating various phase diagrams. The organization of the material on the elements and their compounds is well done, and this makes the volume an excellent reference source. Generally high standards have been maintained throughout publication of the treatise to date, and this volume indicates that they are being maintained.

University of Florida
Gainesville

The Chemistry of the Lanthanides

Therald Moeller, University of Illinois, Urbana. Reinhold Publishing Corp., New York, 1963. ix + 117 pp. Figs. and tables. 12.5 × 19 cm. Paperbound. $1.95.

The editors of the paperback series, Selected Topics in Modern Chemistry, have recognized in the lanthanides an excellent topic for one of their little books intended as supplements to any standard text in first-year chemistry and made a wise choice in selecting Professor Moeller to write the book, since he is a lucid writer and an expert on this topic.

The book is very well planned. The first two chapters cover the subject quite adequately for the reader who is seeking only general information. The third and fourth chapters discuss chemical and technological matters in some detail, and the final chapter briefly presents the actinides as another series of closely related elements whose chemistry has rendered that of the lanthanides no longer completely unique.

Professor Moeller approaches his subject with a historical account that begins with the discovery of an unusual black mineral specimen at a quarry at Ytterby by Swedish Army Lieutenant C. A. Arrhenius in 1787. The unraveling of the complexity of the "earths" named *yttria* and *ceria* is an object lesson in the rewards of infinite patience. The historical account is concluded with a section on the elusive element 61, which was finally identified in materials obtained at Oak Ridge from the fission of uranium by Marinsky, Glendenin, and Coryell in 1947.

In the second chapter the essential uniqueness of the chemistry of the lanthanides is related to the uniqueness of their atomic structure. Here the reader

Always Specify PIONEER Labware For Finest Quality

Made of Corrosion-Free Polyethylene

Extra Tubing Connectors Available

FILTER PUMP

Operates on water pressure from 11 lbs. up All-polyethylene. Integral check valve not affected by fumes or corrosive filtrate. Takes up to 3/8" tubing—connects and disconnects instantly. Has 3/8" IP male thread faucet connection.

$17.40 Per Dozen

BUCHNER FUNNELS

Sturdy two-piece construction. Easily cleaned and unbreakable. Light in weight thus not top-heavy.

Four convenient sizes

BU-43 BU-55 BU-70 BU-90

Priced from $1.75 each in case (12) lots.

From $18.00/case of 72(.25 ea.)

QD CONNECTORS

Two Sizes

A quick disconnect flexible tubing connector. Designed particularly for vacuum applications. Also useful for connecting water lines, manometers, etc. Light in weight and may be used safely in apparatus set ups.

REAGENT DISPENSER

The Safe Way to Handle Acids. Screws on any standard 5 pt. acid bottle and regular gallon or 1/2 gallon jugs. One hand operation delivers reagent at about 1000 ml. per minute. Slight pressure on relief valve stops flow instantly. Priced 3 for $11.25.

Send for catalog of complete line of unbreakable polyethylene labware —sold through leading supply houses.

ENGINEERED PLASTIC LABWARE PRODUCTS

DEPT. J BOX 8066 JACKSONVILLE 11, FLORIDA

learns to identify the lanthanides as the 4*f* elements. Nevertheless, yttrium and lanthanum because of their chemical properties are better discussed with the lanthanides than with any other elements. Scandium is markedly different; even though it was first isolated from yttria, its primary mode of occurrence is not with the lanthanides.

Moeller accounts for the oxidation states of the lanthanides in terms of electronic configuration, insofar as this is possible. The reader is candidly told, and shown, that direct correlation between the two is the exception rather than the rule. The powerful reducing action of the elemental lanthanides is correlated with their large atomic size, as are the pronounced ionic character of lanthanide compounds and the paucity of complex species. Consequences of the lanthanide contraction are discussed, such as the invariable natural occurrence of yttrium with the heavier lanthanides and the small variations in properties that permit separation of the lanthanides by fractional operations.

The third chapter supplements the chemical information already presented by discussing in some detail the general chemistry of the lanthanides in terms of their several oxidation states. This presentation provides the background essential to underatanding the problems of recovery and separation treated in the fourth chapter.

The fifth chapter provides a brief consideration of the actinides. The theme of this final chapter is Seaborg's hypothesis that the elements following actinium constitute a second inner transition series, i.e. that they are 5*f* elements.

The value of this excellent little book, the seventh in the series, is enhanced by a complete index and by a valuable list of selected readings at the end of each chapter.

LAWRENCE P. EBLIN
Ohio University

Nouveau Traité de Chemié Minérale. Volume 8, Germanium, Étain, Plomb

Paul Pascal, general editor. Masson et Cie., Paris, 1963. xxxix + 816 pp. Figs. and tables. 17.5 × 26 cm. 136NF, broché; 148NF, cartonné toile.

Volume 8 of the new treatise by Pascal on inorganic chemistry is to appear in three parts, and it will include the material on the elements carbon, silicon, germanium tin, and lead. Part Three is the only part published to date, and it includes the elements germanium, tin, and lead. With volume 9, this volume, will cover the elements in Group IV.

The section on germanium was written jointly by A. Tchakirian, P. Bevillard, and A. Godfrin. The section on tin was written by B. Lemanceau, except for the material concerning organic compounds of tin, which was written by Pascal himself, and the section on lead was written by R.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Faivre and R. Weiss. Separate paging for each of the three projected parts evidently is intended, as this part has its own paging and indexing, although it is designated as the third part of volume. The tables in the section for tin are used frequently and effectively, and they have excellent bibliographic notes.

As is the case with the entire treatise, bibliographies are listed frequently and contain numerous references. A number of bibliographies might well have been brought closer to the date of publication, and a few do not go beyond 1953, although most are reasonably up to date. The index is far from thorough but a good arrangement in the treatment of each element and its compounds does much to overcome this handicap.

The greatest use of the set undoubtedly will be as a reference tool, but much use can be made of individual volumes and their parts for intensive reading and study as well. This appears to be the case with the material in this part of Volume 8.

ROGER V. KRUMM
University of Florida
Gainesville

Outlines of Biochemistry

Eric E. Conn and *P. K. Stumpf*, both of the University of California, Davis. John Wiley and Sons, Inc., New York, 1963. viii + 391 pp. Figs. and tables. 15.5 × 23.5 cm. $8.75.

An introductory course, and a textbook designed for an introductory course, should prepare the student to proceed to advanced courses and to read, with good comprehension, advanced treatises, monographs, reviews, and the original literature of the subject. Professors Conn and Stumpf have succeeded admirably in their endeavor to prepare a textbook for a one-semester course in biochemistry for upper-division undergraduates and beginning graduate students.

From this book the student can acquire the essential vocabulary and the outlook of modern biochemistry. He will review briefly but clearly certain aspects of organic, analytical, and physical chemistry, that are fundamental to and illuminate areas in biochemistry. Appendix 2 reviews some modern concepts in organic chemistry by definition and example. Appendix 3, Methods in Biochemistry, describes concisely, but not as a laboratory guide, a number of techniques of biochemical research. Chapter 1 reviews *p*H, and other calculations applied to solutions of electrolytes. Appendix 1 reviews logarithms and offers a number of buffer problems. Biochemical Energetics is outlined with reference to free-energy and its determination, oxidation and reduction potentials, and the types of biochemical energy-rich compounds with discussion of the causes of their high negative free-energies of hydrolysis. The chemical nature and structures of the carbohydrates, lipids, proteins and amino acids, and the nucleic acids and their components are [illegible]

The remaining two thirds of the book is devoted to the exposition of the metabolism of biochemical compounds and the integration of metabolism, presented clearly with pertinent diagrams, figures, equations, and schemes for reaction sequences. After the general characterization of the enzymes in one chapter, the individual enzymes, of known metabolic importance, are introduced as the reactions they catalyze are encountered. Vitamins are presented as participants in metabolism with emphasis on the coenzymatic activities of their derivatives and with indication of what is known of those vitamins (K, E, A, D, and C) with no established coenzymatic function. Nutritional aspects of the vitamins are not included.

The authors have concisely presented the salient aspects of the catabolism of the carbohydrates and fats, and the associated and ensuing electron transport and oxidative phosphorylation. The catabolism of the amino acids is briefly indicated. Outlines of the biosynthesis of carbohydrates (including photosynthesis), fatty acids, other lipids, purines, pyrimidines, porphyrins, nucleic acids, and proteins are admirably up-to-date. Digestion, absorption and excretion: the urea cycle, and the nitrogen cycle in nature are outlined. Clear introductions to biochemical genetics and metabolic regulation are especially comment-worthy.

This book, not designed to be exhaustively encyclopedic, provides, in brief compass but in generous measure, a reference "dictionary" for terms, concepts, and reactions of modern biochemistry. As

such it well merits library space. It is well indexed. The authors are to be congratulated for the success they have achieved in writing this well integrated textbook. They have included certain references and the value of the very brief lists is increased by the concise descriptive comment about each book and review article. Supplementary reading should be stimulated. This shorter textbook is highly recommended.

RALPH C. CORLEY
Purdue University
Lafayette, Indiana

Practical Clinical Biochemistry

Harold Varley, Manchester University, England. 3rd ed. William Heinemann Medical Books, Ltd., London, and Interscience Books, Inc. (a division of John Wiley and Sons, Inc.), New York, 1962. viii + 689 pp. Figs. and tables. 14.5 × 22 cm. $0000

According to a statement on the inside cover, the object of this book is to give a comprehensive account of the many biochemical tests now carried out in hospital laboratories as an aid to the diagnosis and treatment of disease. In each chapter there is given at first an outline of various basic principles which lend themselves to the development of testing methods for a particular blood or urine constituent. This is followed by a few selected techniques which are described in detail so that they can be performed without consulting the original articles. Next comes a section in which the significance of the test is discussed and interpretations of the diagnostic implications of a particular result are given in a clear and concise manner. At the end of each chapter there is a list of references which this reviewer finds very useful.

The book consists of 29 chapters, starting with an introductory description of the collection and handling of specimen, notes on colorimetry, and a discussion of control of accuracy, and followed by 28 chapters devoted to various blood and urine constituents.

For those who own previous editions of this book it might be of interest to know that this new third edition contains now a chapter on enzymes (transaminases, lactic dehydrogenase, aldolase, cholinesterase). The chapter on acid-base regulation has been rewritten to include the Astrup techniques. Among other additional newer methods are the glucose oxidase technique for blood glucose, the determination of methylated amines and of hydroxy-methoxy-mandelic acid (in the section dealing with adrenaline and noradrenaline), the d-xylose excretion test, enzyme methods for blood pyruvate and lactate, a technique for the determination of pregnanetriol, and the diacetyl monoxime method for urea.

The author is quite familiar with the recent American literature in clinical chemistry and many of the methods selected have originated here. Nevertheless, there is a distinct British flavor to the book. Some of the apparatus illustrated are hardly, if ever, encountered in the USA and demonstrate nicely that we do not have a monopoly on the manufacturing of precision equipment. A table of normal body weights might puzzle the American reader unless he knows that 1 stone equals 14 pounds or 6.350 kilogram. In contrast to American usage, blood urea is expressed as such (milligram urea per 100 ml. of blood) and not as B.U.N. (milligram blood urea nitrogen per 100 ml.).

Most of the analytical procedures described are similar to or identical with those used in hospital laboratories in the USA. Sometimes, however, one encounters techniques which are unnecessarily cumbersome or outdated. The simple method of Mindlin and Butler for the determination of ascorbic acid in plasma, for example, is mentioned but not described, whereas a more complex procedure is given in detail. The determination of total protein by the copper sulfate specific gravity method is hardly of more than historical interest. In his discussion of non-protein nitrogen determinations the author mentions that trichloracetic acid (instead of tungstic acid) may be used for the preparation of protein-free filtrates. It might be well to add that trichloracetic acid is preferable since it decomposes during digestion into volatile CO_2 and $CHCl_3$, whereas tungstic acid remains and

WHAT GOES ON HERE?

If you do any chromatography at all, it should be the new Lab-Crest needle valve, designed especially for your use. It's not a make-do adaptation, but a brand-new design with the precise control and reproducibility you need.

It takes 12 turns of the new valve to get from positive-zero close to unimpeded (3 mm) open—and there's a reference scale on the stem for hairline accuracy.

The valve will never freeze, never need grease. Its body is precision-bore glass tubing; its needle, Teflon.

You can have the valve either by itself or built right into one of our new chromatography-column bottom connections. (The new connections are more than pretty good themselves: minimum volume between the removable fritted disc and the valve keeps the effluent you're working with from remixing.)

All things considered, the built-in's your best bet, but if you just want the valve itself, fine. We'll be glad to oblige. If you'd like information on either the valve, the bottom connections, or both, let us know.

THE ISI PHILA. CATALOG

lists hundreds of expendable items frequently in need of replacement, such as:

- GRADUATED CYLINDERS
- CHEMICAL THERMOMETERS
- PIPETTES
- TEST TUBES
- HAND CENTRIFUGES
- RUBBER STOPPERS
- CLAMPS
- BUNSEN BURNERS
- FILTER PAPER
- TEST TUBE RACKS

at lowest prices.

If you don't have our catalog, write us and we will fill your request promptly.

PROPIPETTE

Safety Pipette Filler holds liquids indefinitely

- Time Tested
- No moving parts
- Simple to operate

The new PROPIPETTE eliminates the dangerous practice of using the mouth to draw liquids into pipettes. It is simple to use and the operator soon becomes proficient so that liquids can be delivered quickly, precisely and safely. Measurement precision is extremely high (0.01cc). The instrument has three agate-ball valves which operate independently and the entire procedure can be done with only one hand.

Choice of black, red, green, yellow and blue.....PRICE $7.60 each
Available through laboratory dealers. sent on approval

All laboratory pipettes can be used with the PROPIPETTE — Safety Pipette Filler

"I am impressed with your

COLLECTED READINGS in INORGANIC CHEMISTRY

and intend to use it as an auxiliary reference in two inorganic courses which I am teaching"

Inorganic chemical research is moving so rapidly that keeping abreast of developments is increasingly difficult for student and teacher. During the past five years many review articles written specifically to serve this purpose have appeared in the pages of the *Journal of Chemical Education.*

Twenty of the country's most prominent professors of inorganic chemistry indicated the articles they have found most useful; 41 of their most frequent choices have been collected in this volume. Various aspects of Coordination Chemistry are treated by 14 articles. Five deal with Inorganic Polymers, six with Non-Aqueous Systems, and five with topics in Solid State Chemistry. The remainder discuss miscellaneous topics from nucleogenesis to chromatographic behavior of metallic ions.

The popularity of these papers has been demonstrated by the demand for reprints, often far beyond the authors' supplies. The convenience and low multiple-copy price of this volume of collected papers makes it a most valuable supplement to existing textbooks. Every student can now have on his bookshelf the authors he recognizes to be authoritative specialists: Nyholm, Sutton, Bailar, Pearson, Eyring, Audrieth, Burg, Sisler, Honig, Coryell, and many others.

HITACHI PERKIN-ELMER ULTRAVIOLET VISIBLE GRATING SPECTRO-PHOTOMETER

The Model 139 Grating Spectrophotometer, a compact, precise modern instrument, out performs similar spectrophotometers costing significantly more.

Check these features: High resolution grating Monochromator — gives exceptional radiation purity in transmittance / absorbance measurement from 205 to 800 millimicrons; Direct reading meter — presents measurements in both transmittance and absorbance quickly and accurately; Single wide-range phototube — covers the entire range from 205 to 800 millimicrons, eliminates need to change even at wavelength extremes; Dual Hydrogen/Tungsten lamp source assembly — has high energy output, gives instant switching from one source to the other; Direct line-operated power supply — is stable, fully transistorized, eliminating batteries and drift problems; Low cost — brings the advantages of modern instrumentation to any laboratory with unmatched economy and superior performance.

The five basic functional units, in combination, provide the analyst with a fully integrated instrument for the rapid and precise analysis of any sample by absorption measurement.

For details see your Aloe Scientific representative or write Aloe Scientific, ® Division of Brunswick, 1831 Olive Street, St. Louis 3, Mo.

Hitachi Perkin-Elmer MODEL 139 SPECTROPHOTOMETER

- ***Monochromator resolution 0.2 millimicrons***
- ***Range 195 to 800 millimicrons***
- ***Line operated***
- ***Excellent stability***

for immediate shipment from our stock

SPECTROPHOTOMETER, Hitachi Perkin-Elmer Model 139 UV-VIS (Ultraviolet-Visible Range). Diffraction grating type, compact modular construction, completely a.c. line operated, range 195 to 800 mμ, meter indicating directly in transmittance and absorbance, for precise research or control use. Excellent design and workmanship provide an instrument of outstanding accuracy, stability, and versatility.

Wide Range Phototube. A single tube, with detectors of antimony-cesium and silver-cesium, covers entire range from 195 to 800 mμ.

Energy Recording and Kinetic Studies. The exceptional stability of this instrument makes it especially suitable for these techniques.

Linear Wavelength Control. Easily read dial has uniformly spaced divisions over 1 mm wide, corresponding to 0.5 mμ.

Meter Scale Expansion—Absorbance-transmittance meter scale has 10× expansion switch.

Mirrored Meter Scale, 5½ inches long

Performance Specifications

Wavelength range—195 to 800 mμ.
Resolution (monochromator)—0.2 mμ (2Å) throughout range.
Photometric accuracy—better than ±0.5% transmittance; better than ±0.006 absorbance at 0.4 absorbance.
Slits—continuously adjustable from 0.005 to 3.0 mm. Height 20 mm.
Wavelength accuracy—better than ±0.5 mμ throughout range.
Wavelength reproducibility—better than 0.1 mμ.
Photometric reproducibility—better than 0.002 absorbance between 0 and 0.5.
Cell path—5 mm, 10 mm, or 20 mm, in standard, 4-place holder.

9096-E. MODEL 139 SPECTROPHOTOMETER, as described. Complete with a.c. power supply, installed hydrogen and tungsten lamps, 4-place cell holder, matched set of 4 fused silica 10 mm absorption cells, etc. For 115 volts, 50 or 60 cycles, a.c. 2,300.00

REINHOLD textbooks

REINHOLD CHEMISTRY TEXTBOOK SERIES

Consulting Editors: Professor Harry H. Sisler, Professor Calvin A. VanderWerf

Books in Inorganic and Physical Chemistry

DAY and SELBIN
Theoretical Inorganic Chemistry

by M. C. Day, Jr. and Joel Selbin, both of the Department of Chemistry, Louisiana State University

Consulting Editor: Harry H. Sisler
1962. 428 pages. $12.00

"A short and well-conceived book, *Theoretical Inorganic Chemistry*, treating fundamental principles, with only a minimum of descriptive chemistry and intended for an advanced undergraduate or a first-year graduate course. The authors are to be commended for devoting large sections to historical material, not only for humanistic reasons but also to provide a greater appreciation for theoretical concepts."—*Science*

The approach of this widely adopted text is strictly theoretical. The mathematics used is readily comprehensible to senior level students.

CHAPTERS TITLES: Origin of the Quantum Theory/Wave Mechanics/The Periodic Table/Periodic Properties/Chemical Bonding/Inorganic Stereochemistry/Electromotive Force/Acids and Bases/Coordination Chemistry/Nonaqueous Solvents/Theory of the Nucleus/Index.

SANDERSON
Chemical Periodicity

by R. T. Sanderson, Professor of Inorganic Chemistry, State University of Iowa

Consulting Editor: Harry H. Sisler
1960. 340 pages. $8^1/_4'' \times 10^1/_4''$. $9.75

"If there were only one word permitted this reviewer to describe the book 'Chemical Periodicity,' it would have to be 'useful.' Professor Sanderson has incorporated a wealth of information in tables and charts in the text, much of which could otherwise be found only by consulting many different reference works and other sources in the chemical literature. The originality of approach is certain to be of interest."—*Journal of Chemical Education*

This text for upper division and graduate courses in inorganic chemistry offers a stimulating new slant on the relationship between structure and properties and its corresponding applications. A valuable aspect of the text is the collection of more than 60 periodic charts which show at a glance the general trends and relationships among all the elements, with respect to the physical properties of the elements or of their compounds with different non-metals.

SELECTED TOPICS IN MODERN CHEMISTRY

REINHOLD COLLEGE TEXTBOOK DEPARTMENT 430 Park Ave. New York, N. Y. 10022

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Edited by S. Z. LEWIN, New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

XII. Pressure Measurement. Part Three

Seymour T. Zenchelsky, *School of Chemistry, Rutgers, The State University, New Brunswick, New Jersey*

The preceding parts of this article dealt with liquid-column, mechanical, and thermal gauges. This part concludes the article.

Ionization Gauges

Several different kinds of ionization gauges are available, and, in combination, they cover the range of pressures from atmospheric down to 10^{-13} mm Hg. Thus these gauges extend the range of measurement to pressures far below those within the capability of the devices already described. In fact, ionization gauges are indispensable for the measurement of pressures below 10^{-7} mm Hg.

Principle of Operation. All ionization gauges depend upon the measurement of an electric current which results from the ionization of a gas whose pressure is being determined, but the various types differ principally in the method of ion production. For, in order to convert a gas molecule into a positive ion, it is necessary to remove an electron by supplying energy equal to the *ionization potential* of the molecule involved. And this energy—between 4 and 25 electron-volts—may be introduced in a variety of ways, some of which will be described below.

When the requisite energy is supplied at a constant rate, the rate of ion production is also constant, and almost exactly proportional to the pressure of the gas. Thus when the ions and electrons are collected under the influence of a constant potential gradient, the observed current is proportional to the rate of production, and hence to the gas pressure. Ion currents are measured by means of conventional electrometer circuits.

Ion Production. Two methods are commonly used for introducing the energy necessary to ionize the gas: electron bombardment or bombardment by nuclear radiation.

Ionization gauges which utilize the first method fall into two classes: *hot-filament* gauges and *cold-cathode* gauges. The former derive their designation from the fact that electrons are furnished by thermionic emission (as in the ordinary radio tube), while the latter depend upon a high potential-field for the withdrawal of electrons from the (cold) cathode. Since the electron-emission rate is smaller for the cold-cathode type, it is necessary to increase the frequency of collisions between the electrons and gas molecules. This is accomplished by surrounding the gauge with a magnetic field in order to deflect the electrons. Their resultant path is thus cycloidal, rather than linear, thereby increasing their transit time (and hence their probability of collision with gas molecules). Cold-cathode gauges are also designated Philips gauges or Penning gauges.

Figure 37. Simple hot-filament gage.
A—filament
B—anode
C—ion collector
D—ion-current meter
E—system connection

Those gauges which employ radioactive sources to produce ionization are less frequently used than the others because they cover only the range of pressures from 10^{-3} mm Hg to atmospheric. They contain either tritium compounds (beta particles) or radium salts (alpha particles) as the source of ionizing radiation. In both cases the energies of the particles are far in excess of the requisite ionization energy.

Hot-Filament Gauges. The simplest kind of hot-filament gauge is an ordinary triode as shown in Figure 37. Variations in design are chiefly directed toward the following objectives: (1) prolonging element life, (2) minimizing the inconvenience of filament burnout, and (3) extending the lower pressure-limit. Pursuit of the first two objectives has resulted in the use of filaments made of various materials, or of double filaments to permit rapid change-over without removal of the gauge tube. The third objective has led to changes in electrode design and spacing.

Figure 38. Elion Vacuum Gage Control, Model DVG-5. This gage covers the range 10^{-3} mm Hg to 2×10^{-10} mm Hg in six decades. It contains outgassing and filament-protection circuits. Recorder output is available at the rear of the cabinet. Other models are available.

The lower pressure-limit is governed by the magnitude of the observed *residual* current, which is completely independent of the gas pressure. This current results from the ejection of photoelectrons, from the ion-collector electrode, by X-rays which are produced when electrons strike the anode. By means of changes in the physical shape and placement of the electrodes, the number of X-ray photons reaching the collector electrode can be decreased. Thus Bayard, Alpert, and Nottingham were able to decrease the lower pressure-limit from 10^{-8} mm Hg to 10^{-11} mm Hg. Lafferty further lowered this limit to approximately 10^{-13} mm Hg by adding an external magnetic field in order to increase the number of collisions between electrons and gas molecules.

All components of the hot-filament gauge must be thoroughly freed of adsorbed gases prior to use. This is accomplished by heating the tube invelope to 450°C and using either electron bombardment or resistive heating for the electrodes. A serious disadvantage of the hot-filament is its susceptibility to burn-

Demonstrate principles of optics and radiation physics with a modular, low-priced instrument!

Here is a brand new teaching aid—an Educational Spectrometer. The instrument enables you to provide a dramatic demonstration of infrared radiation and the laws that govern its behavior. It can also be used to demonstrate the principles of visible and ultraviolet radiation.

With the Educational Spectrometer, you can demonstrate fundamentals such as transmission, absorption and reflection and perform experiments such as measuring carbon dioxide in the atmosphere. The basic Educational Spectrometer readily accepts additional components for demonstrating experiments of an advanced nature, including studies in ultraviolet and long wavelength infrared.

The Educational Spectrometer is a flexible device consisting of modular components, simple in concept and easy to use. Designed for existing classroom facilities, the instrument encourages student participation. The Educational Spectrometer is supplied with an instructor's guide and comprehensive instruction manual which outlines many experiments.

The list price of the Educational Spectrometer Model ES-100G is $395.00. The price, to qualified educational institutions, is $337.50.

Write or phone for details.

Figure 39. Consolidated Vacuum Corporation, GIC-016 Ionization Gage Tube. It utilizes the Bayard-Alpert construction and incorporates two filaments for rapid changeover in case of burnout.

out in the presence of even moderate pressures of air; thus many gauges provide for automatic cutoff of the filament voltage when the pressure rises above a preset level.

Figure 40. NRC Equipment Corporation, Model 533 Ion Gage Tube. This tube features a platinum coating inside the envelope for electrostatic shielding. It also has a dual filament.

Various hot-filament gauges are available from those companies already listed in Part Two, under *Thermal Gages*. Most of these incorporate a number of the design features mentioned above. They generally use the Bayard-Alpert type gauge tube and indicate pressure on a linear scale, with several decades provided by means of a switch. Most models, other than the least expensive, provide automatic filament-burnout protection as well as provisions for outgassing the electrodes and recorder connection. Typical ranges are 10^{-5} to 10^{-9}, or 10^{-3} to 10^{-10}, mm

SOLID SAMPLER SOLVES TOUGH PROBLEM

To fill the need of a gas chromatograph injector for solid, semi-solid, and crystalline materials, The Hamilton Company called upon Kenneth Dean Parker of the Hine Laboratories, San Francisco, California, to evaluate and test its new Solid Sampler. ▪ Various compounds, solids at room temperature, such as alkaloids, barbiturates, and other solids in toxicological extracts, dissolved in organic solvents were measured onto the tip of the central wire of the Solid Sampler using a Hamilton 701 syringe. The volatile solvent was allowed to evaporate leaving behind the picogram to microgram quantity of solid. The solid was then introduced through the septum of the hot injection chamber with the Solid Sampler. ▪ "The Hamilton Solid Sampler was used one week with excellent performance while injecting drugs, chemical nerve mediators, pesticides, tars, and waxes," reports Parker, "and was found superior to previous experimental models from the standpoint of gas tightness and ease of cleaning." **For your research Hamilton manufactures a complete line of precision syringes, solid samplers, and other related chromatograph equipment.**

NEW! MALMSTADT-ENKE INSTRUMENTATION LAB... IDEAL FOR RESEARCH & EDUCATION IN CHEMICAL INSTRUMENTATION & CONTROL

Complete Lab Station $1100 (Less optional cabinet)

Completely Factory Assembled & Calibrated, This Coordinated System Is Ready To Use... Available As A Complete Lab Or As Individual Instruments!

Whether you're a professional researcher in physical or life sciences, or an educator who's concerned with the teaching of chemical instrumentation, you'll find this low cost Malmstadt-Enke system ideal for providing a solid foundation in the principles, design, and use of electronic instrumentation. Designed by Dr. H. V. Malmstadt of the University of Illinois and Dr. C. G. Enke of Princeton University and engineered and manufactured by Heath, this highly accurate, highly sensitive equipment meets the industry's top standards in form and function. Therefore, experiments are not performed "by analogy" or with gross simplification, but are typical of the best in modern laboratory practice.

Included in this multi-purpose system are factory assembled and calibrated test equipment, new, special-design instruments, special experimental chassis and parts which feature "solderless" spring clip connectors and conventional component layout, plus the authoritative Malmstadt-Enke text, "Electronics for Scientists".

All of the various components may be purchased either as a complete lab station or individually for specific applications. When purchased as a complete station, these instruments offer additional savings over their individual prices. Educational institutions qualify for an additional discount on the entire group as well as individual units. Export models for 115/230 VAC, 50-60 cps are also available; write for details. For a free 8-page brochure describing this system in detail, plus a complete "low acquisition" price listing, simply mail the coupon below.

Servo-Pen Recorder
Worth five times its cost! True potentiometric input; 5 adjustable ranges; 10, 25, 50, 100 and 250 mv plus plug-in connectors for special ranges and applications; rapid chart advance; pen lift; 10" chart; 1 sec. response. 20 lbs.
EUW-20A....$195.00

Operational Amplifier System
Many applications in measurement, computation and control work described in brochure. Self-contained ± 300 V. power supplies, 4 hi-gain, stable, rapid response operational amplifiers, and booster power amplifier. 5-pin connectors. Blank chassis for plug-on circuits available. 18 lbs.
EUW-19A....$135.00

Universal Lab Power Supply
Ideal for circuit design or teaching power supply design; provides many different types of power supply circuits with fast, simple wiring changes. Output 200 to 350 VDC, 0-100 ma, regulated to less than 1% variation. Unregulated output, 100 to 500 V in five steps. 15 lbs.
EUW-15.....$75.00

Voltage Reference Source
Use for calibration, potentiometric measurements, or calibrated bucking voltage. Zener-stabilized, provides ± 1% or 0.1 mv accuracy over range of 0.1 mv to 100 volts. Readout directly on three dials. Coarse and Fine controls. 6 lbs.
EUW-16.....$65.00

Figure 41. Consolidated Vacuum Corporation, Type GIC-110A Ionization Vacuum Gage. It covers the range 10^{-3} mm Hg to 10^{-9} mm Hg on a linear scale in five decades. In addition, the range from 2 mm Hg to 0^{-3} Hg is covered by a thermal gage. More elaborate models are also available.

Hg, usually covered in six decades. Some models also include a thermocouple gauge so as to extend the high pressure limit to one mm Hg. Only a few of the available models are shown in Figures 38, 39, 40, 41, and 42.

Figure 42. NRC Equipment Corporation, Model 763 Combination Ultra High Vacuum Gage Control. This gage covers the range from 10^{-3} mm Hg to 10^{-10} mm Hg in six linear decades. It also has an integral thermocouple gage to extend the range up to 2 mm Hg. This model possesses filament-protection and outgassing circuits as well as recorder terminals. Other models are available.

Cold-Cathode Gauges. These gauges (also called *discharge gauges*) are more rugged than the hot-filament types. The gauge tubes are generally made of metal and they can be cleaned or repaired easily. There are no filaments to burn out upon accidental exposure to high pressure. On the other hand, cold-cathode gauges are not easily degassed and are subject to contamination by breakdown-products from the gas.

Figure 43. F. J. Stokes Corporation, Model DG-10 Cold Cathode Type Discharge Tube. A unique feature of this gage is the ease of replacement of the gage-tube elements and their ease of cleaning. The associated gage control permits coverage of the range from 10^{-1} mm Hg to 10^{-6} mm Hg.

(Illustrated: New Portable Speedservo. Flush Panelgraph with 8" x 8" front also available.)

New Portable Speedservo

(fast, sensitive, simple, versatile)

New, high-speed, high-capability Portable Speedservo—another new generation "Graphline" instrument from Esterline Angus—designed to handle *all* your recording needs, tomorrow's as well as today's.

High Speed: ⅛ second full scale response. Records 4 cycle signals without significant attenuation. **Sensitive:** 0-1 MV DC without jitter. Many higher ranges. Accuracy ½%. **Versatile:** Accommodates DC circuits with output impedance 100,000 ohms or less. Portable unit features sloped stainless steel writing surface. Chart tear-off bar. Full 6" wide 100' long chart. **Convenient:** Dial 14 chart speeds from ¾" per hour to 6" per second. Input terminals, multi-range and feed selectors mounted at front for convenience. Hinged doors provide easy access to writing system and re-roll mechanism. **Less Maintenance:** Simple linear motion pen motor (unique *shuttle* type, not rotary); no strings, no pulleys. Zener reference voltage. Infinite resolution potentiometer prevents hunting.

In addition to the new Speedservo, the radically new EA "Graphline" of rectilinear recorders includes both single and two-channel DC Microammeters, DC Milliammeters, AC or DC Ammeters or Voltmeters, plus inkless and ink-type event recorders. *Your inquiry is invited.* If desired, Esterline Angus will gladly adapt standard instruments to your needs, or develop new ones for you. *Write for new "Graphline" Brochure.*

ESTERLINE ANGUS INSTRUMENT COMPANY, INC., Box 596JC, Indianapolis 6, Indiana

ESTERLINE ANGUS

Excellence in instrumentation for over 60 years

The lower pressure-limit of an ordinary discharge gauge is about 10^{-7} mm Hg (for reasons identical with those given for the simple hot-filament gauge). This

Figure 44. Consolidated Vacuum Corporation, GPH-001 Discharge Vacuum Gage Tube. The permanent-magnet collar is encased in plastic "to protect against loss in strength due to contact with surrounding steel objects."

limit was dropped to 10^{-12} mm Hg by Redhead, who redesigned the gauge tube and used crossed magnetic and electric fields externally in order to decrease the X-ray background.

Figure 45. Consolidated Vacuum Corporation, Type GPH-100A Discharge Vacuum Gage. This control, used with the GPH-001 gage tube, provides a range from 2.5×10^{-2} mm Hg to 10^{-7} mm Hg on three nonlinear scales. More elaborate models are available.

Many models are available commercially. Some are equipped for multi-station operation as well as for recording and control. Some of these are shown in Figures 43, 44, 45, and 46.

Figure 46. NRC Equipment Corporation, Model 752 Redhead UHV Ionization Gage Control with 551 Gage and Magnet. An extremely sensitive gage, using crossed electric and magnetic fields, This model provides a range from 10^{-4} to 10^{-13} mm Hg on a linear scale of nine decades. Recorder terminals are provided and no outgassing of the electrodes is required.

BUCHLER INSTRUMENTS

Rotary Evapo-Mix

Evaporate Multiple Fraction Cuts Directly From Test Tubes in 10-20 Minutes!

FEATURES:

- Internal variable voltage transformer controls vibration rate.
- Simultaneously evaporates 10 test-tubes or centrifuge tubes, 16-25 mm. diameter.
- Connects to efficient water aspirator as vacuum source.
- Automatic thermoregulator controls temperature of water bath.
- Controlled circular vibration creates deep swirling to prevent "bumping" during heating under vacuum.

PRICE COMPLETE with Pyrex Manifold $436.00

with Stainless Steel Manifold $444.00

With the Rotary Evapo-Mix it is possible to achieve in a single test-tube evaporation rates for water of 1.0 ml/min., ethanol, 4.2 ml/min., methanol, 4.5 ml/min., ethyl acetate, 7.2 ml/min., and for acetone, 10.0 ml/min., with all 10 test tubes attached, evaporation decreases approx. 25%.

Request Bulletin J-3-2100 for complete details.

BUCHLER INSTRUMENTS

Water Booster

Eliminates the Hazards of Inadequate or Fluctuating Water Pressure which can mean the Loss of Valuable Time and Material!

FEATURES:

- RAISES and HOLDS PRESSURE at 40 psi.
- Provides 2 independent and Powerful Aspirators.
- Noiseless in operation—continuous duty—needs no maintenance or replacement parts.
- Can be installed without any plumbing or building alterations.

For 110-115V 60 cycle only $249.00

For laboratories where water pressure is low or uneven . . . on upper floors of tall buildings . . . in rural or undeveloped areas. . .
Complete with overload-protected ⅓ HP, single-phase, induction-type motor, water turbine, stainless-steel water reservoir tank, 2 polyethylene water aspirators, 16″ long, 10″ wide, 23″ high.

Request Bulletin J-2-9000 for complete details.

Nuclear-Emission Gauges. The only commercially available gauge using a radioactive source to produce ionization is the NRC Equipment Corporation, Model 553 Alphatron gauge. It covers the range from atmospheric pressure down to 10^{-4} mm Hg in seven decades on linear scale. This gauge is shown in Figure 47. Although the source of radioactivity is enclosed, the ordinary precautions must be observed. (Some states require licensing of all radioactive sources above a specified minimum.) The chief advantages of this type of gauge are the linearity of readings at the high-pressure end of the scale as well as its ruggedness.

Figure 47. NRC Equipment Corporation, Model 530 Alphatron Vacuum Gage. This gage covers the range from atmospheric pressure down to 10^{-4} mm Hg in seven linear scales.

All of the above gauges are calibrated to read directly for dry air, but—as with the thermal gauges—they require a correction for other gases.

Laboratory Evaporation

Coors offers a complete range of casseroles, dishes, capsules and plates for laboratory evaporation. These pieces have been created to match the exacting requirements of working chemists who require especially high quality, uniformity and reliability. Standard items include flat bottomed dishes, such as the #160 capsules, #182 casseroles, #431 and #470 dishes. A wide variety of shallow, curved bottom dishes are also available. These include the #430 regular evaporation dishes, #170 capsules, #180, #181, #190 casseroles, and the #440 and #450 dishes. For dry organic precipitates by evaporation and absorption, the #760 porous plate is offered. A complete selection of Coors laboratory evaporation equipment is immediately available through your laboratory dealer.

the last time we saw Mr. LaPine· he was in Köln

His destination—E. Leybold's Nachfolger, where a line of world-famous high vacuum pumps is being manufactured for distribution in the U. S. through LaPine Scientific Company.

As president of the LaPine Scientific Company, Mr. LaPine travels often to foreign lands, regularly visits American manufacturing plants, to examine and discuss at first hand the instruments, equipment and supplies you will find in LaPine catalogs and brochures.

And in the Chicago, New York and Berkeley, California offices and warehouses of the LaPine organization, a staff of equally dedicated men are also constantly on the lookout for the finest in scientific products to meet your needs.

LaPine is big—big enough to maintain its own specialty items manufacturing facilities, its own instrument testing and service department and an installation department ready at all times to install equipment in your laboratory or plant. Big enough to stock for your convenience a vast array of physics, chemistry and teaching apparatus in a wide choice of models and brands. Yet LaPine has never deviated from its basic concept of personal service to its customers.

For you, this means an always reliable source, whatever your requirements—an organization established in 1937 to bring to the scientific community, to schools and to industry, the most advanced, most sophisticated, yet most practical and economical equipment and supplies.

You are cordially invited to write for comprehensive catalogs or for detailed information on specific items.

moduline

a new Aerograph series

Hy-Fl$_2$ • 202 • 1520

Will your next gas chromatograph be driveable?

The law requires that all new cars sold must be sufficiently complete to allow them to be driven. No such law protects the unwary gas chromatograph buyer.

You may need to buy, for instance, a storage battery, or for a small additional fee of $150—a built-in power supply. Flow controllers for two-column instruments will be provided for only $300. There are other little items which you can also dig up here and there, such as gas connecting tubes, filters, flow meters, septums, transformers, restrictors, etc.

As a sales inducement, Aerograph instruments are provided with those accessories necessary for its operation. A display of accessory items for the new Aerograph Hy-Fl$_2$ is shown on page 4.

The question is—who should take care of these little things?

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

The Hy-Fl$_2$
with a single column and multiple detectors

A modular concept provides the option to use and to interchange functional components.

The Hy-Fl$_2$, a single column gas chromatograph fulfills this requirement.

It may be used with any of the four common detectors or as a two-channel instrument with combination electron capture and flame detector. Either a manual or linear programming module may be selected.

Electrometers, single or dual channel, are interchangeable. Many accessories are available.

Single Cabinet Construction

1. Harmful heat from the ovens in the unitized cabinet is dissipated with a separate cabinet fan.
2. The short stainless steel injector permits on-column or vaporized injections to be made with standard Hamilton syringes with 2" needles.
3. The same motor circulates column oven air and also rapidly cools the column when the door is opened.
4. The column and detector ovens are thermally isolated from each other by glass wool and a moving air current.

Single cabinet construction saves valuable bench space, and allows permanent electrical connection to be made without cumbersome electrical cords and plugs necessary with the common multi- cabinet design.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

The 202 & 1520
with dual columns, and dual flame & TC detectors

Both the Aerograph 202 and 1520 Moduline instruments contain dual columns with proportional flow controllers and flow meters. The separate detector oven is precisely held at any temperature with full proportional heat control.

The all stainless column oven, heated by an 800 watt coil, will program at 30°C/min to 400°C and will cool from 400 to 100°C in four minutes.

The injectors are heated separately. Temperature readout on an accurate pyrometer reads column oven, injectors, detector oven, collector, and one auxiliary plug. An upper oven temperature limit control on all Moduline instruments protects columns and equipment from accidental overheating.

202

The Aerograph 202 incorporates either dual flame or dual input TC detectors. It may be used with the manual temperature programmer or the linear programmer (LP) modules. The LP is electronic without gears, motor, or clutch. A switch and matrix plug provide any programming rate desired.

1520

The 1520 is a more deluxe version of the 202. It contains both the dual flame and thermal conductivity detectors. The detector choice is made by re-connecting the downstream ends of the columns. The exclusive Aerograph matrix temperature programmer is standard. This deluxe programmer not only gives complete flexibility in pre-setting temperature programming rates but automatically closes the oven door after cool-down and re-establishes the start temperature.

Represented all over the world

This beautiful instrument comes with the accessory items shown above.

1. Stainless steel column (substrate optional)
2. 24 injection gaskets
3. 6 extra O-rings for flame tip
4. Hydrogen tank line, ⅛" copper, with fittings
5. Nitrogen tank line, ⅛" copper, with fittings
6. Restrictor, for regulating hydrogen flow rate
7. Nitrogen filter, stainless steel with molecular sieve
8. Air pump for air supply to flame
9. Air filter, stainless steel, molecular sieve
10. Soap bubble gas flow meter
11. Electrical cords for AC and recorder

You will also be interested in these bonus features standard with Moduline instruments.

- Separate detector oven, full proportional control
- 2" injector adaptable to Pyrex inserts and columns
- Special thermocouple and variable power plug for auxiliary equipment
- Capillary tube sample collection—with flame and EC detectors
- Differential flow controllers for carrier gas
- Many accessories, including hydrogen generator available

These new instruments are being described in current house publications, Aerograph Research Notes and Previews and Reviews. Write for your free Gurukul Kangri Collection, Haridwar subscription.

CENCO'S NEW ANALYTICAL BALANCES

A. SOLID TITANIUM BEAM / JEWELED MECHANISM: beam surfaces can't flake—lose weight—as do plated beams. Synthetic ruby knife on synthetic sapphire plane, jeweled bearings at all critical points for long-term accuracy. **B. POSITIVE, CHAIN-DRIVEN WEIGHT CONTROL:** stainless steel chain not affected by environment or age, no cord-and-pulley drive to slip. Ring weights are stainless steel, corrosion resistant, non-magnetic, precisely calibrated. NBS Class "S" weights used in models 1581 and 1582; "S-1" in model 1580. **C. ALL-METAL HOUSING:** durable, rugged, minimum dust attraction. Heavy, multiple-coat baked enamel finish. **D. EASY-VIEW WEIGHING CHAMBER:** non-corroding base impervious to chemical attack. Crystal clear glass walls highly resistant to scratching, will not discolor. **E. EFFICIENT, NON-FATIGUING CONTROLS:** simple, speedy operation through natural, straight-line movement of operator's hands from side loading of sample to controls manipulation. With hands off to side, operator always has clear view of readout. **F. EASIER, MORE ACCURATE READOUT:** fixed vernier with cursor for quick, accurate readout.

Fully Accessible Pan

One Weight Knob

Plus-Minus Scale

Tare Indicator

Rapid Dial Taring

10 Gram Optical Range

Reading Device for Rapid Weighing-in

P120

A new top-loading balance with ± 3 mg precision

For the first time a balance offers the ruggedness and easy accessibility of a top-loading pan, the fast readability of a 10 gram optical scale and precision of ± 3 mg, capacity 120 g.

It is ideally suited for technical analyses, preparatory chemistry, weighing-in, serial checkweighing, batching and weighing-out.

If you would like to try this new balance, or want more detailed information, contact your Mettler dealer now, he will be glad to arrange a demonstration or trial.

Now why are we making Stoppers

For the same reason any established company expands into a related area. We see a future for superior stoppers — a great, growing future, especially in the laboratories of schools. The experiments of tomorrow's scientists cannot be automated. We intend to supply them with the finest laboratory products our know-how makes possible. Yes, stoppers are a modest product — but they remain a mighty **necessary** modest product in today's laboratories — and tomorrow's.

We have had a century of experience at Easthampton Rubber Thread Company in a highly exacting field. We have put all of that experience plus our extensive research facilities into developing a line of superior stoppers. Today we present these stoppers to you. We honestly feel they are the finest ever offered.

There are three basic grades for your use, each in your choice of solid, one-hole, and two-hole types:

GRADE M29 BLACK RUBBER

Even a staple can be improved. Greater rubber formulation results in a softer, more resilient stopper. This low-cost, high-quality product answers most laboratory requirements. The softer bounce of more rubber means better sealing, prevents breakage and freezing.

GRADE M18 PURE GUM

Isoprene gives greater uniformity, resiliency, and clarity. This man-made rubber equals nature's best — plus improving resistance to extreme temperatures, high and low. Pure gum is less than 4% extractable — can be sterilized, keeps its shape for exceptionally long life. Safe and clean, it **floats** — never bobbles.

GRADE M35 GREEN NEOPRENE

Now sulphur-free green replaces black neoprene. This strong, new stopper withstands 150°C temperatures — remarkably resists petroleum products, sunlight, oxidation, heat, gas, flame, and oils of all kinds.

All grades are being produced from brand new molds on new equipment. Hence you get a better finish, a smoother surface . . . constant, controlled quality. All come to you in five-pound packages, and the convenient shelf-saving one-pound pack, if you prefer. All are backed by Easthampton's century-old reputation for leadership, quality, and service you can count on.

Molded Products stoppers are part of a complete line of products for industrial and educational laboratories, including cylinder guards, crucible holders, dropper bulbs, and stopper ties. They're available now at your laboratory supply house. For free samples and full information, write Department RLS at Easthampton.

Corkless chem class . . .

The reason? Kontes Kem-Kits!

Why have many schools switched to ground jointed Kem-Kits for their beginning organic chemistry courses?

Here are a few comments from instructors and students:

"We saved hours of set up and take down time." "We were able to perform 25 to 30% more experiments with your kits." "Student interest in lab work increased." "Ground joints mate better . . . hold a much tighter vacuum." "Safety records have improved . . . breakage has been reduced." ". . . contains all the glass apparatus students need for this course." "With cork equipment this set-up takes me over an hour . . . with your glassware . . . about 8 minutes." ". . . no accidents whatsoever." ". . . greater student pride." "Breakage was negligible." "Chemical costs have been cut in half." "Glassware seems heavier . . . sturdy, top quality." "Good package idea (polystyrene) . . . ideal way to store." . . .

We could go on . . . acceptance has been unanimous and with good reason. Kem-Kits contain the same type of glassware your students will be required to use after graduation.

There's much more you should know about Kontes Kem-Kits: The several kit types available. How only fifteen parts enable such a variety of set-ups. Why ultimate cost is less than cork equipped labs. For complete information send for Bulletin 962-R.

Multi-channel Pulse Analyzers?

TMC covers a wide spectrum of PHA requirements. From modular mega-channel, multi-parameter systems, to versatile, portable units — TMC offers the broadest, most complete line of pulse analyzers available. Key features of each system are listed here, but fully detailed data is available in specific product bulletins. Contact the TMC branch office nearest you or write the main office for the bulletins you wish. Technical Measurement Corporation, 441 Washington Avenue, North Haven, Conn., CE9-2501

DOMESTIC: Gardena, Calif.; San Mateo, Calif.; La Grange, Ill.; Silver Spring, Md.; Stoneham, Mass.; White Plains, N. Y.; Oak Ridge, Tenn.; Dallas, Texas.

IN CANADA: Allan Crawford Associates, Ltd., 4 Finch Avenue, W., Willowdale, Ontario, Canada.

IN EUROPE: Technical Measurement Corporation, GmbH, Mainzer Landstrasse 51, Frankfurt/Main, Germany.

IN JAPAN: Nichimen Company, Ltd., Muromachi, Nihonbashi, Chuo-Ku, Central P.O. Box #1136, Tokyo, Japan.

TMC

TECHNICAL MEASUREMENT CORPORATION

Multi-parameter Analysis

16,384-channel system with modular assembly permits adaptation of this system to varied requirements including simultaneous analysis of two sets of input pulses. Plug-in input units are provided for selection of Pulse Height or Time-of-flight analysis in either of two parameters. Data are displayed on a CRT in "map", "isometric", or "slice" modes. Data may be stored in many sub-groups, either manually or by external routing signals.

Basic Components: 2-parameter Input Unit with logic plug-ins for PHA or TOF; Coincidence Detection Unit; Memory Control Unit; 16,384-channel ferrite core Memory; Display Control; Automatic Programmer; Readout Equipment.

Multi-parameter Analysis

4096-channel system with modular construction includes the two-input unit with logic plug-ins for 2-parameter coincidence or singles studies — Pulse Height Analysis, Time-of-flight or both. Digital baseline and range switching permits up to 256X magnification of a selected area of the spectrum. For example, the experimenter can select various 4096-channel address configurations from a 1024 x 1024 (mega-channel) spectrum.

Basic Components: 2-parameter Input Unit with PHA or TOF plug-ins; Memory Control Unit; 4096-channel Memory; Coincidence Unit; Format Selector; Display Control; Automatic Programmer; Readout Equipment.

Digitized by Arya Samaj Foundation Chennai and eGangotri

Multi-purpose Pulse Analysis

Model CN-1024, 1024-channel pulse analyzer provides a choice of interchangeable plug-in logic units for rapid conversion to different types of Pulse Height analysis; Time-of-flight studies; Pulsed Neutron studies; Mass Spectrometer analyses; Multiscaler operation; or Coincidence Pair Spectrometer operation. Display Control Unit, when used with Coincidence Pair Spectrometer plug-in, provides significant "map" display of data.

- **Basic Components:** 1024-channel Memory; Logic Plug-ins; Display Control Unit; Data Output Unit; Readout equipment.

Multi-purpose Pulse Analysis

Model CN-110, 256-channel multi-purpose pulse analyzer employs interchangeable plug-in logic units identical to those used in the CN-1024 system: Pulse Height Analyzer; Time-of-flight; Pulsed Neutron; Multiscaler; Mass Spectrometer; Coincidence Pair Spectrometer. Provides for analog, digital, and binary readout with various accessory equipment. Totally transistorized circuitry on plug-in cards results in compact, bench-top size and 25-watt power requirements. Accessories include Data Output Unit, and numerous readout control devices.

Portable Multi-channel Analysis

Model 404, 4-input, 400-channel pulse analyzer with accessory Resolver/Integrator and high speed printer. The versatile portable 400 Series analyzer is ideally suited for activation analysis and similar identification applications. It provides for data storage in memory groups of 1 of 400 channels, 2 of 200 channels or 4 of 100 channels ∴ data transfer from half to half or quarter to quarter in the same half. 3″ CRT provides analog display. Analyzer is compatible with paper tape punch, reader, IBM typewriter and digital printer readout devices. **Resolver Integrator** has push-button operation, performs as resolver or integrator without need for intermediate tape equipment. As a resolver it makes data available from any analyzer memory quarter or half and adds to or subtracts from data in adjacent quarter or half. Permits removal of individual components of a spectrum. As an Integrator, it integrates memory data within any channel band from 0 to 399 in either of two modes. **Printer unit** prints out channel no. and data at high speed — 5 lines per second — on 3-inch paper tape. Built-in high voltage supply will power as many as four detectors.

Neutron Generator for Activation Analysis

Ellison Activatron-110, 150 KV neutron generator is a simple, effective, low cost unit that will produce 14 MEV neutrons from a Deuteron-Tritium reaction. Neutron yield is greater than 10^{10}n/sec. Uses unique ion source derived from 150 KV accelerating voltage which permits entire ion source and accelerating tube to be immersed in an oil tank. Compatible with TMC 400 series pulse analyzer and accessory units.

$1.24/PT. $1.24/PT. $1.19/PT.

To Chemists who think that Merck quality costs extra

It doesn't. Merck Chemicals may set the standards that others attempt to follow—but who can put a price tag on quality? In fact, there are many examples where Merck customers actually *save* money, and still do not have to sacrifice the extra quality. A quick look at the comparative price chart will show you that it really pays to specify Merck when ordering standard chemicals. And if your need is for something special, again it is smart to specify Merck. The production of specific chemicals for specific analytical jobs is a Merck specialty.

For your copy of the Merck Laboratory Chemicals Catalog, plus the name and address of your nearest Merck supply house, write to: Quinton Company, Division of Merck & Co., Inc., Rahway, N.J.

MERCK CHEMICALS SAVE YOU MONEY

FOR EXAMPLE:

PRODUCT	SIZE	Consumer Prices Per Pt. MERCK	BRAND B	BRAND M
Chloroform Reagent (A.C.S.)	5 pt.	$1.19	$1.24	$1.24
Acetone Reagent (A.C.S.)	8 pt.	$ .48	$ .54	$ .52
Methyl Alcohol Anhydrous Reagent (A.C.S.)	8 pt.	$ .44	$ .48	$ .48
Isopropyl Alcohol Reagent	8 pt.	$ .51	$ .56	$ .53
Carbon Tetrachloride Reagent (A.C.S.)	5 pt.	$ .97	$1.05	$1.00
Toluene Reagent (A.C.S.)	8 pt.	$ .45	$ .49	$ .48

Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ A complete line of Absorption Cells for spectrophotometers manufactured in the Common Market is being imported by Scientific Cell Company. The line includes standard rectangular and cylindrical types as well as flow cells, semimicro, and microcells. They are of completely fused construction, matched into sets of two or four and color-coded for ease of identification. The Cells are available for measurements in the far-ultraviolet range down to 165 millimicrons, through the ultraviolet, the visible, near-infrared, and the infrared ranges up to 3.6 microns. Descriptive bulletin, price sheet, and name and address of your local SCC distributor are available from Scientific Cell Co., 70–20 Austin St., Forest Hills, New York 11375.

▶ For complete information on IEC Maxiforce bottles for high speed, high volume centrifugation, and other plastic containers write to International Equipment Co., 300 Second Ave., Needham Heights 94, Massachusetts.

▶ Gerald K. Heller Co., P.O. Box 4426, Las Vegas, Nevada, offers a new S-250 solid state motor controller. Input voltage 208–240 a.c., single phase with output of 200 v dc, for field.

▶ Carl Zeiss, Inc., 444 Fifth Ave., New York 18, N. Y., announces the availability of the particle size analyzer TGZ 3, providing the highest degree of automation possible for the analysis of all particles in a mixture, including those which overlap or are irregularly shaped. In a typical mixture, 1000 particles can be analyzed in 48 different size categories in approximately 15 min.

▶ Linayer Corp., 201 Ford Building, Detroit 28, Michigan, offers a series of versatile instruments called "Quantab." They are available to measure rapidly, concentration of salt and total acidity and alkalinity in various ranges.

▶ Techne Ltd., 661 Brunswick Pike, Princeton, New Jersey, has available the "Tempette" for applications requiring temperature control in the range of 2 tenth of 2 degree.

▶ Any isothermal gas chromatograph now can be easily converted into a versatile, dual column temperature programmed instrument by adding the new, low-cost Loenco Model 150 oven accessory. Write for Data Sheet LOE-21—Loenco, Inc., 2092 N. Lincoln Ave., Altadena, California.

▶ Aero Geo Astro Corp., Lincolnia and Edsall Rds., Alexandria, Virginia, offers a new differential controller as an economical means of obtaining precise temperature control in laboratory enclosures.

▶ A special hand-operated, deck-top emergency spray has been designed by Haws Drinking Faucet Co., 4th and Page Sts., Berkeley, California, for immediate first aid to counter eye, face and body contamination. Haws Model 8902 is designed for the laboratory or classroom where work with potentially dangerous chemicals or fire is involved.

▶ A new low priced precision 6 inch electromagnet, specifically designed for research applications, is now available from Alpha Scientific Laboratories, Inc. P.O. Box 333 Berkeley 1, California. The design incorporates a one piece frame, cast of high grade magnet steel, to provide a field of 8000 gauss in a 2 in. gap with 6 in. pole faces, and 12,000 gauss with a $^3/_4$ in. gap.

(*Continued on page A874*)

"practically indestructible"...

. . . that's the way Dr. E. J. Durham, director of New York University's Nichols Laboratory describes U. S. Stoneware lab sinks. Today, after more than 35 years of service, the "U. S." lab sinks installed when Nichols Laboratory was built are just as good as new. Not one has ever had to be replaced.

N.Y.U.'s experience is typical of that of several thousands of users of "U. S." Chemical Porcelain Laboratory Sinks — users whose sinks will, almost without exception, outlast the buildings in which they are installed.

Time-proven "U. S." Chemical Porcelain Lab Sinks will handle safely all acids, alkalies, caustics and solvents— weak or strong, hot or cold. Thus, there's no need for corrosion charts . . . no need for special sinks for special corrosives.

Mechanically strong and rugged, "U. S.' Chemical Porcelain sinks will stand up under all the heat-shock and physical abuse they'll ever meet in ordinary lab usage. Non-staining and scratch-resistant, they're as easy to clean as a china dish. And . . . they're available in three attractive colors to match any decor.

Your Laboratory Furniture Manufacturer can give you complete information. See him, or write for your free copy of Bulletin L-10.

OHAUS®

TRIPLE BEAM BALANCE

MODEL 760 with undivided tare beam

LIST PRICE $24.50 w/o att. weights

MODEL 707 ATTACHMENT WEIGHTS $5.50

ONLY OHAUS HAS 2610 GRAM CAPACITY BUT . . .

There are many other reasons why those who weigh their decisions carefully SPECIFY OHAUS! Here is a precision balance suited to a wide range of general laboratory and industrial applications. Exclusive OHAUS versatility makes available undivided tare beam and poise, avoirdupois standards, plus a choice of commodity platters. Choose plate, removable pan or scoop of stainless steel or even a 9″ dia. x 5″ deep animal subject box. Stainless Steel relief etched tiered beams, and epoxy enamel finishes assure maximum corrosion protection. Readings are faster with true sliding type poise which eliminates secondary beam oscillations. Readings are more accurate because end reading device eliminates parallax error. Add these to other features experience has taught us you demand and we are confident you will also choose OHAUS . . .

94 the LEADER WHO INVITES COMPARISON!

▶ F & M Scientific Corp., Avondale, Pennsylvania, announces the availability of a new component collection system for gas chromatography. Designated the Model TCS-3, the unit represents a significant advance over previous collection methods since it allows 100% positive collection of both the component effluent and carrier gas and is not dependent upon the condensation of a solute from a moving gas stream.

▶ Digital, eyelevel readout and an illuminated auto-indicating vernier are featured in the Model 160 B high speed, single pan analytical balance recently made available by the Voland Corp., 27 Centre Ave., New Rochelle, New York.

▶ Two new low-cost gas chromatographs Model 810 and 820 of unusual flexibility and performance have been announced by Perkin-Elmer Corp., Norwalk, Connecticut. For many applications, the instruments are said to be fully as useful as units of twice their cost.

▶ Literature, samples and prices of a new steel tubing clamp for laboratories, is available from Penn-Chem Corp., 232 N. Marshall St., Lancaster, Pennsylvania.

▶ A new combination gas chromatograph and gas thermal conductivity analyzer has been developed by Atomic Laboratories, Inc., 3086 Claremont Ave., Berkeley 5, California. Designed primarily for demonstration purposes in the science classroom and laboratory, the instrument can also be used for various chemical research and analyses.

▶ An analytical balance with 1200 mg. optical range, plus or minus 0.05 mg. precision, and direct reading to 0.1 mg. has been introduced by Mettler Instrument Corp. 20 Nassau St., Princeton, New Jersey, for laboratory, production control and school application.

▶ A new, low cost data acquisition system has been announced by Bausch & Lomb, Rochester 2, New York, providing a rapid, precision method for analyzing and recording colorimetric samples. The inherent accuracy of the system is due largely to the fact that component units have been specifically designed to function together in an integrated manner. As a result, ease and speed of operation permit technicians to produce a valid record in a matter of seconds.

▶ The Houston Instrument Corp., 4950 Terminal Ave., Bellaire 101, Texas, offer the HLVC-150 log voltmeter converter which gives accuracy over a 70 db range. 70 Db corresponds to a range of 1 mv to to 3.16 v or 100 mv to 316 v; either range is selectable with an attenuator.

▶ Applied Research Associates of Texas, Inc., 6541 N. Lamar Blvd., Austin 5,

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Texas, offer a remote measurement electronic thermometer. Remote 6 sec liquid temperature measurement to 1° accurate to 500 ft is convenient with the Model FT-2 ARA electronic thermometer.

▶ A miniature precision air sample pump has been developed and perfected for personnel monitoring and atmospheric sampling. Model S440 miniature sampler is powered by a 6 v rechargeable nickel cadmium battery capable of 8 hr. of continuous sampling. Write Union Industrial Equipment Corp., Port Chester, New York, for information.

▶ A compact new combined temperature/power-control center with proportioned output is now being produced by the Research, Inc. Controls Division, P.O. Box 6164, Minneapolis, Minnesota. The complete control module consisting of a temperature-indicating pyrometric controller and a solid-state power proportioner is called the Thermac Model MPR 7822.

▶ The General Scientific Equipment Co. has announced a new line of heavy-duty unit first aid kits designed to facilitate emergency treatment through the use of unit-wrapped items, boldly labeled and arranged for immediate recognition and access.

Each G-S Unit-Type Kit has a facsimile index on the inside of the case lid which shows at a glance the exact location of all items and gives concise instructions for their use.

Cases are made of 20-gauge steel, finished in either olive green or grey baked-on enamel. Integral mounting brackets and carrying handle permit the kits to be used for permanent wall installation or portable service.

Complete information may be obtained by requesting Bulletin 305 from General Scientific Equipment Co., 7516 Limekiln Pike, Philadelphia 50, Pennsylvania.

▶ A nearly maintenance-free electric steam boiler has been developed by the Hot-Shot Division, Automatic Steam Products Corp., 3-7 W. 61st St., New York 23, N. Y. The new Hot-Shot electric boiler was developed for the Oak Ridge National Laboratory for use in a distillation process to produce Oxygen 17—a "clean" isotope used in bio-medical research. The distillation process at Oak Ridge is expected to run night and day for two or three years before production of Oxygen 17 begins at full enrochment. The Hot-Shot boilers were designed to run for 26,280 hr in continuous operation without being shut down for maintenance. Detailed information about these boilers is available by writing to the Hot-Shot Division.

▶ Phoenix Precision Instrument Co. announces a new color-monitoring device for continuous flow applications. The

Phoenix Flow-Colorimeter Model 600, was especially designed for monitoring of column effluents in chromatographic applications, where wide concentration ranges and minimum mixing are of major importance. This instrument incorporates a voltage stabilizer, a filter turret for convenient change of monochromatic filters, a dual-sensitivity glass absorption cell, a precision cell positioning device and a 570 mμ peak wavelength interference filter. A 10-turn shunting potentiometer for full scale adjustment of the photocell output signal is also incorporated. The Flow-Colorimeter can be used with almost every commercially available indicating or recording device.

Boekel LABORATORY OVENS

for Sterilizing, Drying, Conditioning, Preheating, etc.

UNEXCELLED for PERFORMANCE and DURABILITY

No. 1078A

THE WORLD-POPULAR 1078A DRYING OVEN—*provides these features:*

• Polished stainless top and control panel. • Polished stainless steel framework. • Strong spotwelded frame. • Set-in door construction. • Rigid high-insulation-value walls. • Adjustable bottom ventilators. • Bimetallic thermostat, control switch and pilot light. • Working chamber inside 18¼″ high x 17″ wide x 14¼″ deep. • Explosion proof door catch with streamlined chrome handle. • Galvanized expanded metal shelves, bound with stainless steel. • Overall outside dimensions 25-⅝″ x 18¼″ x 17½″ deep. • Heavier insulation; temperature range to 200°C. • 1500 watt heaters. • AC only—specify 115 volt or 230 volt.

SMALLER SIZE 1078—*or, 1078G, with heat-resisting glass door:*

• Asbestos door, stainless steel top and frame. • ⅜″ thick Marinite for temperatures up to 200°C. • New bimetallic thermostat mounted in heating area for better sensitivity and easy adjustment. • Temperature control ±1°C. Inside dimensions, usable space 9″ high x 11¼″ wide x 9½″ deep. • Outside dimensions 14-¾″ high x 12¼″ wide x 11½″ deep. • 660W heating units located in bottom, readily accessible for replacement or changing from 115 V. to 230 V use. • Supplied with a three-wire cord and plug. • AC only—specify 115 volt or 230volt.

A Long-Term Investment for laboratories, Boekel Constant-Temperature Ovens offer many desirable features, such as: Corrosion Resistant Polished Aluminized Steel or Stainless Steel spot-welded bodies and frames with asbestos exterior panels. • Double Wall Construction with non-settling rock-wool insulation. • Uniform Heat Distribution by strategic location of coils and efficient baffling . . . coils operate at black heat for maximum efficiency and longer life. • Constant Temperature within range 35° to 200°C maintained by Robertshaw hydraulic thermostat . . . sensitivity ±1°C. • Individual On-Off Switch permits maintenance of thermostat setting for succeeding tests. • Strong, Well Supported, Insulated Doors with positive locking door, two-point latch and thick asbestos gasket, minimizes heat loss. • Sturdy, Heavy Gauge Shelves are self-supporting even when partially withdrawn.

No. 1066

TWO METALS AND THREE SIZES TO CHOOSE FROM:

No. 1066 Double door. Aluminized steel. Inside dimensions: 25″ high x 31″ wide x 19″ deep. Outside dimensions: 38½″ high x 38″ wide x 28¼″ deep. Capacity 8.5 cubic feet. Three removable shelves. Consumes 2000 watts.

No. 1066S. Same as 1066 except all metal parts of stainless steel.

No. 1065 Single door. Aluminized steel with all metal door. Inside dimensions: 12″ high x 12″ wide x 12″ deep. Outside dimensions: 24½″ high x 18″ wide x 19″ deep. Capacity 1 cubic foot. Two removable shelves. Consumes 600 watts.

No. 1064 Single door. Aluminized steel. Inside dimensions: 18″ high x 24″ wide x 14″ deep. Outside dimensions: 32″ high x 31½″ wide x 21″ deep. Capacity 3½ cubic feet. Two removable shelves, one stationary. Consumes 1200 watts.

No. 1064S Same as 1064 except all stainless steel including entire door.

ALSO AVAILABLE

GAS-HEATED, HOT AIR STERILIZERS—made of stainless steel (triple wall), thermostatically controlled. Further information on request.

● *Facts & Methods For Scientific Research* is available from F & M Scientific Corp., Avondale, Pennsylvania. The Spring issue (Vol. 4 No. 2) consists of twelve pages devoted to new applications and techniques in analysis by gas chromatography.

● A sixteen page illustrated brochure *Bulletin No. AC-6297* that describes the Series 350 digital operation system is available from Electronic Associates, Inc., Long Branch, New Jersey. This computer is the digital portion of the Hybrid 2000, a hydrid digital/analog computer.

● *Bulletin SR-3* illustrates and describes in detail the three SR-type recorders from the designer and manufacturer, E. H. Sargent & Co., 4647 W. Foster Ave., Chicago 30, Illinois: Model SR and Models SR-20 and 30 and Model SRL.

● A new 6-page Norelco folder titled *X-ray Microscopy in Sharp Focus*, giving operating principles and application data for such instruments, is available from Philips Electronic Instruments, 750 S. Fulton Ave., Mount Vernon, New York.

● Associated Technical Services, Inc. announces the publication of a new and angotri bibliographic tool—the 1963 *Science, Technology and General Dictionary Catalogue*. This well-indexed catalogue serves as a reference to and source of hundreds of currently available technical dictionaries in 35 languages from all over the world. The catalogue is 35 cents. Payment in coins or stamps is acceptable. Write Associated Technical Services, Inc., Dictionary and Book Division, 855 Bloomfield Ave., Glen Ridge, New Jersey.

● The August issue of the *Gas-Chrom Newsletter* (available from Applied Science Laboratories, Inc., State College, Pennsylvania) describes a method for modifying conventional diatomaceous earth supports which can then be used as adsorbents for gas-solid chromatography.

● Arthur H. Thomas Co., P.O. Box 779, Philadelphia 5, Pennsylvania is now distributing Vol. 1, No. 3 of their bulletin *Scientific Apparatus*. The 20-page bulletin illustrates and describes important new Thomas developments and current offerings of manufacturers for whom they are distributors.

● (Order the following from the Superintendent of Documents, U. S. Government Printing Office, Washington 24, D. C.) *Calculations of the Potential and Effective Diffusion Constant in a Polyelectrolyte Solution*, by Sam R. Coriell and Julius L. Jackson; National Bureau of Standards Technical Note 192; June 28, 1963; 29 pages; 25 cents. *Refractive Indices and Densities of Aqueous Solutions of Invert Sugar*, by Carl F. Snyder and Albert T. Hattenburg, National Bureau of Standards Monograph 64; June 7, 1963; 6 pages; 15 cents. *Radiobiological Dosimetry: Recommendations of International Commission on Radiological Units and Measurements*, National Bureau of Standards Handbook 88; April 30, 1963; 16 pages; 25 cents.

● An 8-page folder available from John P. Mickel Associates, Inc., 158 S. Rochester Rd., Clawson, Michigan, describes: gases pure to one part per million or less; gas chromatographs sensitive to one part per million or less; gas purifiers that clean to one part per ten million; sample crushers that make possible the analysis of trapped gases such as bubbles in glass as small as two millionths of a milliliter; a 48-hr service on gas analysis sensitive to one part per million or less.

● The new, condensed Welch "Duo-Seal" Vacuum Pump Catalog includes illustrations, descriptions, performance curves, specifications, and prices of their complete line of vacuum pumps. It shows single-stage and two-stage, oil-sealed, rotary pumps; combination, mechanical-diffusion pumps, and their new, ultrahigh vacuum, turbo-molecular pumping unit. The complete Welch line of pumps cover a range of capacities from 21 to 8400 liters per minute (air) and ultimate pressures from 2 × 10 mm Hg (torr) down to 1 × 10 mm Hg (torr) or better. Catalog will be sent on request to The Welch Scientific Co., 1515 Sedgwick St., Chicago, Illinois 60610.

(*Continued on page 881A*)

The news about the very low net cost of TIAA life insurance is sometimes slow in getting to new college staff members—TIAA doesn't have soliciting agents.

But when they do hear, people who are eligible have a way of making up for lost time. The average size TIAA policy bought during 1962 was for $21,000. And more than half of the life insurance issued that year was to "satisfied customers coming back for more."

Eligibility for TIAA life insurance is open to all employees of colleges, universities, private schools, and certain other nonprofit educational or scientific institutions. If you're eligible, use the coupon below to request a copy of TIAA's new Life Insurance Guide and a personal illustration of low-cost TIAA insurance at your age.

DICTATOR!

In the selection of laboratory glassware the lowly Bunsen Burner becomes a veritable dictator. It dictates your choice of expensive heat-resistant borosilicate ware or the less costly, but equally efficient, lime glass.

If you plan to use glassware in conjunction with a Bunsen Burner, specify heat-resistant glassware. If not, specify Diamond D Laboratory Glassware and use the savings to purchase additional lab supplies.

It's as simple as that!

New Mini-Lab Brochure

27 new items get your copy!

Ace Mini-Lab is truly the small economy size: it takes up less space, considerable saving in reagent chemicals is effected *and* the good design of Ace Mini-Lab will facilitate your work. Mini-Lab is the first especially designed and fully developed line of miniature glassware. It has been enthusiastically accepted in laboratories, in schools, everywhere. It is versatile, comes in ₮ 14/20 and ₮ 18/9 joints, and features a full line of component parts permitting endless variations. For the small economy size, try Ace Mini-Lab. The excellent design, the fact that the reduction in size has been accomplished without reduction in usefulness, will make Ace Mini-Lab the most satisfactory miniature glassware you have ever worked with.

New Mini-Lab Brochure just out! Write Dept. J for your copy!

WATER DE-MINERAL-IZERS

Ideal for School Laboratory use and Classroom demonstration.

Portable • Low Cost • A Size For Every Need

DEEMINIZER

In use throughout the world as laboratory standard. Capacity up to 5 gals. per hour. Comes complete with direct-reading electric quality-check meter. Reservoir supplies processed water for instant use. Gravity flow insures consistent quality. DEEMINIZER® CL-5-115V/60C $39.50. Carton 6 DEEMINITE Resin Filters-$11.70.

Deem-a-Jet

The world's lowest cost, high capacity de-mineral-izer. Faucet connected—water pressure operated. Multi-jet feed. De-ion-izes tap water—fast—up to 2 gals. per min.—120 G.P.H. Use it for immediate volume needs—or intermittently. DEEMAJET® Model 128 complete with resins · $39.50. Extra DEEMINITE® Resin Refill Units-$21.00.

DEEMINAC

Fill quart bottle with tap water and invert on holding stand as shown. Operates unattended. Gravity flow—2 to 3 quarts per hour—insures consistent quality. DEEMINAC® Model SD-326 complete with metal stand, graduate and cover—$6.95. Extra Filters (A-6) $4.00. Demineralizer only, without stand, etc. DEEMINAC Model 32-6-$5.75. Other DEEMINAC models from $1.75.

● A new 16-page bulletin on Multichannel Analyzers is now available from Packard Instrument Co., LaGrange, Illinois. *Bulletin 1032* provides complete descriptions and specifications on Packard Models 15 and 16 400-channel analyzers. Included are descriptions of operating modes of the analyzers, with typical oscilloscope traces; an explanation of analyzer operations at various voltage/channel combinations, together with schematic diagrams; and methods of automatic programming. For a copy of *Bulletin 1032*, write Packard Instrument Co., Inc., Box 428, LaGrange, Illinois.

New Chemicals

◊ Information on "Sephandex" a cross-linked detran material as spherical beads for column packing may be obtained from Pharmacia Fine Chemicals, Inc., 501 Fifth Ave., New York 17, N. Y.

◊ Chrom-Line Labs, P.O. Box 1231, Kansas City, Missouri, offer "Molecular Sieve Flour" for work in gas chromatography.

◊ Cesium metal with the increased purity of 99.97 per cent is now available from The Dow Chemical Co., Midland, Michigan. Production process improvements have reduced maximum impurities from 0.07 per cent to 0.03, decreasing the cesium's content of other alkali metals and oxygen.

◊ A solder glass kit containing powdered glass and a liquid suspension vehicle is being marketed by Corning Glass Works, Corning, New York, as an aid to college laboratories and other high-vacuum research facilities.

◊ United States Testing Co., Inc., 1415 Park Ave., Hoboken, New Jersey announces the introduction of a new line of high purity spectographic grade chemicals to be marked under the brand name "Spectroline."

Miscellany

★ Dr. Herman Liebhafsky surveyed the fuel cell problem for his colleagues in the Summer issue of General Electric's *Research Laboratory Bulletin*. Attention was focused on the approximately 25 million being spent for research in this area and the variety of interrelated chemical engineering difficulties that are involved.

★ Are you aware of Hydroscan? The use of such a system for continuous monitoring of total water in moving solids is discussed in *CEC/Recordings*, second quarter 1963.

★ Applications will be accepted through January 3, 1964, for National Science Foundation Graduate Fellowships for advanced study in the sciences. To be eligible for Graduate Fellowships, applicants must be citizens or nationals of the United States and have demonstrated ability and special aptitude for advanced training in the sciences. Fellows will be selected on the basis of ability as attested by letters of recommendation, academic records, scores achieved in the Graduate Record Examinations, and other appropriate evidence of potential ability for scientific study or work. Application material for National Science Foundation Graduate Fellowships may be obtained from the Fellowship Office, National Academy of Sciences National Research Council, 2101 Constitution Ave., N.W., Washington, D. C. 20418. Awards will be announced on March 15, 1964.

★ An Advanced Research Conference will highlight a week, February 3–7, 1964, devoted to gas chromatography at the University of California, Los Angeles. Dr. Robert L. Pecsok, Professor of Chemistry, announces a program of distinguished chemists who will discuss "Progress in Gas Chromatography," emphasizing their own work. On the conference program for February 3 and 4 are: Dr. J. H. Purnell, University of Cambridge, England; Dr. Charles N. Reilley, University of North Carolina, Chapel Hill; Dr. Paul Boyer, University of California, Los Angeles; Dr. James C. Sternberg, Beck-

man Instruments, Inc., Fullerton; and Dr. Evan C. Horning, Baylor University, Houston.

The sixth short course in "Fundamental Principles of Gas Chromatography" will be held February 5–7. This intensive three day course is presented in response to many requests from industry and is an up-dated version of the very successful previous courses. It is aimed primarily to instruct personnel from industry, although it may be equally valuable to persons in academic or government laboratories. The approach will be non-mathematical, stressing theory only to the extent necessary to understand the practical aspects and to obtain optimum results.

The two programs are independent and both are jointly sponsored by the Department of Chemistry, Engineering Extension, and Physical Sciences Extension, with Dr. Pecsok as the Coordinator. Fee for the two day Conference will be $25, and for the three day Course $100. Additional information and application blanks may be obtained by phoning or writing to H. L. Tallman, Physical Sciences Extension, Room 6532 Engineering Building, University of California, Los Angeles 24, California (272-8911, extension 3121).

Attendance at both programs will be limited with selection on a first come first served basis.

★ You can now buy a top-quality pocket slide rule at the price you would expect to pay for ball-point pen. This all plastic slide rule has the same kind of engraved scales and tongue and groove construction found on more expensive slide rules and nine different scales, C, D, CI, B, A, K, S, T, and L. For additional information contact Dyna-Slide Co., 600 S. Michigan Ave., Chicago 5, Illinois.

★ The National Science Foundation announces the next series of closing dates for receipt of proposals for Basic Research in Life Sciences, January 15, 1964 and Renovation and Construction of Graduate-level Research Facilities, December 1, 1964. Proposals received prior to these dates will be reviewed and notification of the Foundation's action will be made within four months. Inquiries or proposals requesting support should be addressed to the National Science Foundation, Washington, D. C. 20550.

★ The National Science Foundation will again offer fellowships for Secondary School Teachers of Science and Mathematics to several hundred teachers, for summer study beginning in 1964. The fellowships will be awarded competitively on the basis of the candidate's ability to carry out an individually planned graduate level program in the mathematical, physical, or biological sciences.

An applicant for a Summer Fellowship for Secondary School Teachers must be (1) a citizen or national of the United States, (2) a science or mathematics teacher in a secondary school, with at least three year's experience in that capacity, and (3) a holder of a baccalaureate degree or its equivalent. Information and application materials may be secured by addressing a request to NSF Secondary School Teacher Fellowships, American Association for the Advancement of Science, 1515 Massachusetts Ave., N.W., Washington, D. C. 2005. Completed applications must be received by the Association by January 3, 1964.

★ Applications for the NSF Postdoctoral Fellowship Program will be accepted through December 16, 1963. To be eligible for Postdoctoral Fellowships, applicants must (1) be citizens or nationals of the United States, (2) possess special aptitude for advanced training, and (3) have obtained the doctoral degree prior to beginning tenure or have the equivalent education and experience. Postdoctoral Fellows will be selected on the basis of ability as evidenced by letters of recommendation and other appropriate evidences of scientific competence. Application materials may be obtained by writing to the Fellowship Office, National Academy of Sciences, National Research Council, 2101 Constitution Ave., N.W., Washington, D. C. 20418. Completed materials must be received not later than December 16, 1963.

IKA
UNIVERSAL
AUTOMAT

MICRO COMBUSTION TRAIN

permits faster and more accurate determinations of C, H, N, O, S and Halogens with controlled temperature to 1200°C.

Both heaters are hinged for easier insertion and removal of combustion tube and to provide faster cooling.

All controls are on the front panel with separate temperature indicators for long and short heaters. The heater elements are imbedded in ceramic to prevent breakage and oxidation.

The Universal Automat may be used for semi-micro determinations by merely interchanging heaters.

SPECIFICATIONS

Long heater 200 mm. Provides temperatures up to 1200°C within 20 minutes. Cooling time from 1200° to 180°C in 10 minutes.

Short heater 45 mm. Provides temperatures up to 1200°C within 8 minutes. Cooling time from 1200° to 50°C in 10 minutes.

Short heater travel time variable from 5 to 30 mm per minute

ALABASTER STATUETTE—SUMERIAN. THE METROPOLITAN MUSEUM OF ART, ROGERS FUND, 1950.

He was a great scientist in his day

This Sumerian was minding our business five thousand years ago.

Like Olin, he specialized in chemicals and metals. He smelted copper and tin to make bronze. He made an iron axle, put it between two wheels, and off he went.

Men have always been trying to find the answers to important problems. Today, Olin is at it, harder than ever.

Our pioneering research in liquid chlorine helped eradicate typhoid and other water-borne diseases.

Our anti-tubercular drug, NYDRAZID®, is a major reason TB deaths decreased 60% in the last eight years.

Olin's ammonium phosphate fertilizer (Ammo-Phos®) makes it possible for farmers to grow more food than ever before.

And to prevent the tremendous waste in food spoilage, we're working on an antibiotic-coated plastic wrapping.

To take a big sting out of life, Olin is developing a high speed cartridge that enables medicine to be injected without the use of hypodermics.

But none of these advances could have been made without our scientists.

Every division of Olin seeks the creative, scientific mind for the answers to the research problems of our day. If this is the kind of work that interests you, call Olin or write to M. H. Jacoby, College Relations Officer, Olin Mathieson Chemical Corporation, 460 Park Avenue, New York 22, N.Y.

Just Published!

8½″ x 11″ Paperback Reprint

TOPS *Tested Overhead Projection Series*

Compiled by
HUBERT N. ALYEA
Princeton University

Insistent demands for copies of the instalments already published in this series have prompted the publication of this initial reprint. It contains all the instalments published in the *Journal of Chemical Education* from January 1962 through August 1963, thus including the articles on the construction of the inexpensive overhead projector and the basic kit of simplified TOPS devices.

Because "Tops in Chemistry" will take several years for complete publication, Dr. Alyea has prepared a special section, exclusively for this booklet, which he calls, "The Top Ten Tops." This lists the ten experiments best suited for projection in each of the 24 topics in his book, "Tested Demonstrations."* By referring to this book and using the data given in "The Top Ten Tops," the teacher will be able to work out his own 240 projection experiments. Eventually these will be described in greater detail in the forthcoming instalments of the TOPS series in the *Journal of Chemical Education*.

48 pages 8½″ x 11″ $1.50 per copy, postpaid

*Tested Demonstrations in Chemistry—208 pp
8½″ x 11″ $3.50 per copy, postpaid

CHEMICAL EDUCATION PUBLISHING CO.
20th AND NORTHAMPTON STREETS • EASTON, PA.

CONTENTS

- Introduction: the projector; the devices.
- Cells: manufacture and use.
- Electrical devices.
- Gas cells.
- Horizontalizer.
- Heat cells.
- Measurements: electrical, pressure temperature, time, volume and weight
- Scales.
- TOPS Experiments:
  1. *Chemical Reactions*
     a) Chemical elements
     b) Mixtures and compounds
     c) Physical changes
     d) Chemical changes
     e) Fundamental laws
  2. *Oxygen*
     a) Occurrence
     b) Preparation
     c) Reactions with Oxygen Gas
     d) Some oxidations
     e) Ozone
  3. *Hydrogen*
     a) Historical
     b) Preparation of Hydrogen
     c) Physical Properties of Hydrogen
     d) Reactions of Hydrogen
     e) Hydrogen Isotopes
- Inexpensive Overhead Projectors.
- Basic TOPS kit of simplified TOPS devices.
- The Top Ten TOPS (240 experiments)

2. PHYSICAL PROPERTIES OF WATER

Aqueous Tension *(Continued)*

Dem. 103—Deliquescence, Using a Balance

To show: The increase in weight of $MgCl_2$ exposed to moist air.

Materials: See-saw balance (SD-20-S); $MgCl_2$, filter paper, plastic cover $5 \times 2^1/_2 \times 1^1/_2$.

Procedure: Project see-saw balance SD-20-S. Fold filter paper into a $^3/_4$-in. square, soak thoroughly in saturated $MgCl_2$-aq., and place on the left pan. Place a similar, dry paper in the right pan. Add water dropwise to the latter, until the balance *just* dips. Cover balance with plastic case.

Observation: Within 30 min, the balance tips to the side where the $MgCl_2$ has absorbed moisture from the air. (Noerdin)

SD-20—A Variety of Balances

The balances pictured below serve a variety of purposes. Balance SD-20-K is a Knife-edge balance useful for accurate measurements. Balance SD-20-S is a See-saw balance useful for showing which of two objects is definitely heavier. Balance SD-20-V is a Visible-scale balance enabling the student to see the actual weights on the screen.

Construction of balances. Balance SD-20-K. Purchase from Edmund Scientific Co., Barrington, New Jersey Catalog No. 0000 Price $15 includes balance and set of weights from 10 g down to 0.1 g. Unscrew metal base and discard. Replace with a plastic box-like base, as shown in the Figure.

Balance SD-20-S. Two nails, points upwards, are set in the plastic base, as shown in the Figure. The see-saw teeters on two small conical holes in which the nail-points rest. The left pan can located in two positions; the right pan can slide along the arm to counterbalance objects placed in the left pan. The keel is added to give stability and strengthen the see-saw. A plastic cover placed over the see-saw protects it against air-currents. (Noerdin)

Balance SD-20-V. This is like SD-20-S but with a clear plastic keel along which two weights can be moved, set in notches. It is less sensitive than SD-20-S but enables the student to read what weights are on the pan. Of course the object and weights must be placed as centrally on the pan as possible.

3. CHEMICAL REACTIONS OF WATER

Dem. 104—Deliquescence and Efflorescence

To show: Change in weight of substances gaining and losing moisture from the air.

Materials: See-saw balance SD-19-S; dry P_2O_5, dry $Na_2HPO_4.7H_2O$, plastic cover $5 \times 2^1/_2 \times 1^1/_2$, filter paper.

Procedure: Project balance. Place pile of P_2O_5 on a $^3/_4$-inch square of filter paper on the left pan, and the $Na_2HPO_4.7H_2O$ on a similar paper on the right pan, to extremely small overweight. Cover with plastic case.

Observations: Balance trips in a few minutes, depending on how closely balanced the two pans are. The P_2O_5 deliquesces and gains weight, the $Na_2HPO_4.7H_2O$ effloresces and loses water and weight. (Noerdin)

Dem. 105—Dehydration of $CuSO_4.5H_2O$

To show: The addition of water to $CuSO_4$, and removal of water from $CuSO_4.5H_2O$

Materials: $CuSO_4.5H_2O$, conc. H_2SO_4, methyl alcohol, H-3.

Procedure: Place equal quantities of $CuSO_4.5H_2O$ (blue vitriol) in 3 culture tubes. Add water, conc. H_2SO_4, and a quarter-tubefull of water to one, of conc. H_2SO_4 to the middle one, and of methanol to the other. Stir.

Observations: The aqueous solution is blue due to hydrated cupric ion. In concentrated H_2SO_4 anhydrous $CuSO_4$ is formed and falls as a powder to the bottom of the tube; the supernatant liquid is colorless. With methanol the copper salt dissolves to give a clear green complex. (Noerdin)

Dem. 106—Heat of Hydration of Lime

To show: Heat evolved when unslaked lime (CaO) is treated with water (slaked).

Method 1.

Materials: Fresh lumps of CaO, iodine flakes, H-4 Grand Canyon, medicine dropper.

Procedure: (*a*) Fill coke cap with lumps of CaO, place on H-4 and project. Add a few drops of water to the CaO. (*b*) Repeat, but this time place a few flakes of iodine in the cap, and rest this on a pile of smaller, fresh, lumps of CaO. Add 1 or 2 ml of water to the lime.

Observations: (*a*) The heat of hydration of the CaO is sufficient to generate a cloud of steam, visible on the screen. The lumps of CaO are seen to crumble. (*b*) Heat sufficient to sublime the iodine (over 180°C.) is generated, and violet clouds fill the screen.

(*Chris Kato, Lillian Munson, Randy Kay, Lakeside Summer School, Seattle, Washington*)

Method 2.

Materials: Wide mouth 2-oz glass bottle, M°, fresh CaO. (CARE: Do not use plastic box).

Procedure: Place gas thermometer bulb inside of the glass bottle, and half-fill with lumps of CaO. Project. Add a few ml of water. (CARE: Violent evolution of steam).

Observations: There is a dramatic rise in temperature.

EASTMAN G848 Propyl Alcohol
EASTMAN G212 iso-Propyl Alcohol
EASTMAN G325 Toluene
EASTMAN G2396 2,2,4-Trimethylpentane

The "G" stands for gas chromatography, the means of final purification that gives us strong confidence that these are the purest of all liquid EASTMAN Organic Chemicals and a strong suspicion that they are the purest liquids available from a commercial house. Sure, with nothing better to do for a few months and nobody asking questions about outlays for equipment, a good physical chemist could work up a sneer at that word "commercial." He could possibly also work up 5 ml of any of these compounds constituted of molecules more homogeneous in some respect or other than are ours. Ours carry a green label. They are intended as standards. You may conceive of less static uses. We expect that each transaction will involve individual correspondence and explanation of the g.c. curve for the particular batch, a document we shall furnish with the vial. It's knowing precisely what you are getting in the vial that has to be worth the price. Neither the liquid nor the information is worth much without the other.

The list of "G" liquids can be expected to grow. Ask for our latest list of them. Inquiries should be addressed to Distillation Products Industries, Eastman Organic Chemicals Department, Rochester 3, N. Y. (Division of Eastman Kodak Company). The cost to us of any discussion that does not result in an order is on the house, alas.

Thoughts to buy tape by

There is a new magnetic tape. Intended for those who record sound for a living instead of just for fun, it is now coming into stock at electronics supply houses. These dealers, however, consider it none of their business whether the tape is needed for fun, profit, or the general betterment of the human race.

There are two main points of novelty:

1. We suspend our iron oxide needles in a new binder, which is adaptable only to our highly proprietary and unbeatably clean and uniform method of manufacturing sound tape. Excellent as the generally used poly(vinyl chloride) may be for the purpose, our binder seems not only to age with demonstrably more grace but it forms a smoother top surface (which is widely known to reduce intermodulation distortion, for reasons never wholly understood). The needles do not aggregate in it in the usual wood-grain-like pattern, nor do they get battered and fractured in the attempt at homogeneity of distribution. Therefore print-through measures a whole 55 db down from the recorded signal in the standard test, and this in turn greatly extends the time between periodic rewindings that tape-recordings should get.

2. The support is not the super-strength kind but cellulose triacetate, treated to make it stronger than triacetate has any business being. Amateur recordists generally don't realize when they buy super-strength that the low-tension equipment used in the home never requires it, though it costs something in audio uniformity and money. Professionals with their high-tension equipment, on the other hand, have long known that in case of trouble, a clean break is instantly apparent, remediable, and preferable to the treacherous stretch—over 70% before breaking—of the super-strength stuff. (Our treated triacetate stretches no more than 0.5%. We trademark it DUROL Base.)

Didn't you know we made magnetic tape? Ask for EASTMAN *Type A303. (Type A304 has a thicker coating for higher output with less amplifier gain and its attendant noise. It is recommended only for commercial recording of originals on adjustable-bias equipment.)*

Radiometry of the epidermis

Policemen often moonlight. Many male schoolteachers moonlight. Work by the light of the moon to supplement one's income can be honorable, stimulating, and even necessary. When an astronomer (whose professional concerns encompass moonlight) wants to moonlight, he acquires some KODAK IRTRAN 4 Optical Material from Apparatus and Optical Division, Eastman Kodak Company, Rochester 4, N. Y. and fabricates it into a small converging lens. This transmits infrared from 1 to 20μ, a band wherein falls nearly all the energy emitted by sources around 300°K. Knowing that the human epidermis is normally a 310°K emitter, he builds the lens into a portable instrument for measuring temperature variation over small epidermal areas without actual contact and the error so introduced. He arranges for the lens to image a small area on a thermistor in a bridge circuit with microammeter. The lens makes the response independent of exact distance.

After permitting use of this instrument in clinical practice for several months, the moonlighting astronomer sounds like this:

> A female who had Raynaud's disease was scanned 5 days after 2 fingers had been amputated to the first joint. At the site of amputation the indicated temperature was lower than 2 cm back from the end of the wound. The surgeon wouldn't use a skin thermometer for fear of causing an infection in the open wound.
>
> A female presented herself with a small mass at the outer quadrant of the right breast; palpable with difficulty. It showed a 0.7°F rise in the area. She was hospitalized and a biopsy performed. An adenocarcinoma was found and removed.
>
> An elderly male with a deformed, ulcerated lesion of the right ear cartilage was examined. An 0.5°F increase over the involved area was noted. It was resected and a basal cell carcinoma was found.
>
> A female came in with psoriasis which gave rises of about 1°F over the involved areas. It was inflamed. It is notable that temperature elevations are not obtained over static cases of psoriasis.
>
> A 17-year-old female with a soft mass in the left breast presented herself. The reading was 0.5°F cooler than the surrounding tissue. One week later surgery showed that it was benign.
>
> A male was burned on the right leg. The leg was bandaged. On the third day an elevation in body temperature was noted, suggesting an infection. On scanning the bandage a reading at the knee showed a 2°F rise. On removal of the bandage the infection site was verified.

The only way currently to learn anything further about this line of development is to inquire of The Dudley Observatory (Chartered 1852), 140 South Lake Avenue, Albany, N. Y.

CHEMICAL PROJECTS

Research Ideas for Young Chemists

Compiled by **JAY A. YOUNG,** King's College, Wilkes-Barre, Penna.
JOHN K. TAYLOR, National Bureau of Standards, Washington, D. C.

An Inexpensive Coulometer for Titrations with Externally Generated Reagents

See HEAD, W. F., JR., AND MARSH, M. M., *J. Chem. Educ.*, **38**, 361 (1961).

The products formed when a solution of sodium sulfate is electrolyzed are sulfuric acid and sodium hydroxide. A buret constructed in the form of an inverted "T" is fitted with two platinum electrodes, one in each arm of the "T." As a solution of sodium sulfate is allowed to run out of the buret during electrolysis, acid will run out of one arm, and base from the other. The total amount of acid, or base, formed during electrolysis is conveniently measured by a coulometer, for which a wiring diagram and constructional details are described.

Hence, by collecting either the electrolytically formed acid, or the base, in a flask containing base, or acid (the unwanted electrolysis product is discarded), and a suitable indicator, a titration can be performed. The coulometer is turned off when the indicator changes color, and the amount of acid or base generated and therefore collected in the titrating flask is noted from a dial reading on the coulometer.

By selecting other electrolytes other titrants can be electrolytically generated. For example, iodine from a solution of potassium iodide, lithium methoxide from a solution of lithium chloride in methyl alcohol are suggested in the article.

Question:

Construct the coulometer and special buret. Select a problem from another project in this series which requires a titration as part of the procedure for the solution of the problem, and perform the necessary titration coulometrically.

A Thermobalance for Student Experiments

See BOTTEI, R. S., AND GERACE, P. L., *J. Chem. Educ.*, **38**, 568 (1961).

Many substances lose weight when heated, either by partial or complete decomposition into gaseous products or by reaction with the air to form gaseous products. In thermogravimetric analysis, a substance is slowly heated from room temperature (usually) to higher temperatures of about 300°C, or even higher, while being continuously weighed. A graph showing the weight of the substance as a function of temperature can be used to interpret the reactions which occur when the substance is heated.

For example, the graph for copper sulfate pentahydrate shows more than one break, indicating that the water is driven from this salt in steps; that is, not all five water molecules are held with equal strength.

The article describes the modification of an ordinary analytical balance so that it can be used for thermogravimetric analysis. Although the authors used a magnetically damped balance for this modification, this feature is not essential. Also, it is not necessary to provide a nitrogen atmosphere for the furnace used in the heating. Instead of the Temco input controller, a manually operated rheostat or autotransformer could be used, or see M. M. MARKOWITZ, ET AL., J. CHEM. EDUC., **38**, 96 (1961) for a simple motor driven variable transformer. Another type of balance, using a strain gauge as the sensitive element, is described by W. W. WENDLANDT, J. CHEM. EDUC., **38**, 566 (1961).

Question:

Select one or more substances, or mixtures of substances, which you think will change weight when heated and determine the weight loss curve by thermogravimetric analysis. Interpret the curve you obtain, and confirm your ideas concerning the chemical changes which take place by further laboratory studies.

A Simplified Isoteniscope

See STEINBACH, O. F., AND DEVOR, A. W., *J. Chem. Educ.*, **22**, 288 (1945); *ibid*, **22**, 496 (1945).

The isoteniscope is a convenient instrument for the measurement of vapor pressures of liquids over an extended temperature range. The apparatus described in the first reference is a simplified design that could produce vapor pressure measurements of a research quality.

Essentially the apparatus consists of a boiling flask containing a thermometer and an outlet side arm which is provided with a U-tube trap all immersed in a water bath. This vessel is connected to a manometer, a ballast bottle, and a water aspirator pump to vary the pressure of the system. The water bath is heated and the pressure at which ebullition just ceases is measured as the vapor pressure of the liquid at the temperature indicated by the thermometer. The only complicated part of the apparatus is the series of bulbs constituting a trap and these could be eliminated provided the investigator was careful in his manipulation of the external pressure.

The authors discuss sources of error and illustrate the performance of the apparatus by measurements of the vapor pressures and calculations of derived heats of vaporization for five compounds. Agreement with the literature is excellent, the maximum error indicated for the heat of vaporization being 2.6 per cent. The second reference by the same authors describes a micro-modification of the apparatus that gives results of comparable or higher precision with as little as 0.5 ml of sample.

Questions:

Construct an isoteniscope as described in the references, measure the vapor pressures and calculate the heats of vaporization of representative compounds.

What improvement could you suggest that might improve the reliability of the measurements obtained with this apparatus?

Use the apparatus to measure the boiling points of a number of "pure" materials. Devise purification procedures or collaborate with others engaged in such activities and utilize your apparatus for measurements of the purification procedure.

from abstract ideas . . . fundamental knowledge at Esso Research

Existence of the "cage" effect, an important concept in solution kinetics, has been confirmed directly by two Esso Research chemists, Dr. Richard K. Lyon and Mr. Donald H. Levy.

The Franck-Rabinowitch cage effect is the reverse of the diffusion controlled recombination reaction. Two highly reactive species, A and B, may react with each other so readily that the rate of reaction of an initially separate pair A and B is controlled by their diffusion towards each other. Conversely, if A and B are produced very close together (for example by the reaction $AN_2B \rightarrow N_2 + A + B$), they may react with each other before they can diffuse apart. Figuratively, as depicted in the illustration, the solvent molecules form a cage holding the reactants together. Numerous observations have been explained by invoking this "cage" effect with varying degrees of certainty.

In the experiments at Esso Research, mixtures of azomethane and d_6-azomethane were photolyzed both in gas phase and in isooctane solution. Primary steps formed CH_3 and CD_3 radicals, followed by hydrogen abstraction to methane or recombination to ethane.

Gas phase recombination occurs randomly among methyl radicals forming ethane in proportions such that $(CH_3CD_3)^2/(C_2H_6)(C_2D_6) = 4$. In solution, however, no detectable CH_3CD_3 forms, but appreciable C_2H_6 and C_2D_6 do form, experimentally proving the "cage" effect.

Separate experiments have shown "cage" effects occurring in high pressure gas phase, the diffusion coefficient being somewhat larger than in solution. These hitherto unknown "cage" effects may have a marked influence on high pressure gas phase reaction kinetics. Consideration of this effect in both high pressure gas phase and solution reactions may have great significance in determining the optimum conditions for new or existing chemical processes.

FILTRATION CHART

for use in chemical analysis

relative retention values

OF S&S ANALYTICAL FILTER PAPERS

Our laboratory pioneered new methods for the quantitative evaluation of filter papers which have proved of considerable help to the chemist in the standardization of their speed and retention ranges.

This retention method, employing a finely divided dispersion, assigns numerical test group values to S & S filter papers — for equal precision with very fast, loose textured grades and sheets of greatest density.

The wide range of this novel retention scale, and the diversity of S & S filter papers, are represented graphically on the sedimentation cylinder. The graphic representation is illustrative of the general range of retention of S&S Analytical Filter Papers. For additional copies of the S&S Filtration Chart, address Dept. JCE-311.

Always Specify PIONEER Labware For Finest Quality

Made of Corrosion-Free Polyethylene

Extra Tubing Connectors Available

FILTER PUMP

Operates on water pressure from 11 lbs. up. All-polyethylene. Integral check valve not affected by fumes or corrosive filtrate. Takes up to 3/8" tubing—connects and disconnects instantly. Has 3/8" IP male thread faucet connection.

$17.40 Per Dozen

BUCHNER FUNNELS

Sturdy two-piece construction. Easily cleaned and unbreakable. Light in weight thus not top-heavy.

Four convenient sizes

BU-43 BU-55 BU-70 BU-90

Priced from $1.75 each in case (12) lots.

From $18.00/case of 72(.25 ea.)

QD CONNECTORS

Two Sizes

A quick disconnect flexible tubing connector. Designed particularly for vacuum applications. Also useful for connecting water lines, manometers, etc. Light in weight and may be used safely in apparatus set ups.

REAGENT DISPENSER

The Safe Way to Handle Acids. Screws on any standard 5 pt. acid bottle and regular gallon or 1/2 gallon jugs. One hand operation delivers reagent at about 1000 ml. per minute. Slight pressure on relief valve stops flow instantly. Priced 3 for $11.25.

Send for catalog of complete line of unbreakable polyethylene labware —sold through leading supply houses.

PIONEER PLASTICS, INC.

ENGINEERED PLASTIC LABWARE PRODUCTS

DEPT. J BOX 8066 JACKSONVILLE 11, FLORIDA

WACO LO-TEMP BATH

COOLS HEATS

ONLY...$440.

SEVEN WAYS BETTER

1. Heats and Cools—almost double the range of the average visibility bath.
2. Accuracy — constant temperature at any level from −10°C to +65°C ±.01°C — ideal where precise temperature control is required.
3. Large Capacity — coils fit snug against the bottom, the entire volume of the jar is usable. Glass jar permits fast observation.
4. Compact — only 20½" wide 27½" high. Saves space. Fits on any lab table or desk.
5. Self-contained — heating controls, cooling compressor, all parts are housed in this compact unit.
6. Low Maintenance — Waco Lo-Temp has been proved trouble-free by laboratories from coast to coast.
7. Low Price — $440.00.

Specify: No. 882 Waco Lo-Temp Refrigerated Bath, complete with Pyrex jar 12" in diameter, for 115 volt 50/60 cycle AC

Other sizes and accessories available to fit your needs. Write for Waco Bath Bulletin for complete information.

HIGH VACUUM Duo-Seal Mechanical and Diffusion Pump

★ **HIGH VACUUM—0.001 Micron GUARANTEED**
(0.000 001 mm Hg)

★ **CAPACITY AT 0.1 MICRON—600 Liters Per Minute**

★ **MATCHED PERFORMANCE**

No. 1392 Patent No. 2337849

EACH ELEMENT WITH TWO-STAGE CONSTRUCTION

WATER-COOLED OR AIR-COOLED MODELS

- **ECONOMICAL TO RUN AND MAINTAIN**
- **QUIET OPERATION**

$320.00
Complete with Motor

This is an unusually convenient portable diffusion-pump unit, employing a two-stage mechanical pump and an unbreakable, all-metal diffusion pump. The two components are properly matched as to performance and together will produce a vacuum of better than 10^{-6} mm without the use of cold traps. Complete with oil for both pumping elements.

Other combinations are available with speeds up to 16,500 liters per min. at 0.1 micron. We will gladly submit full details describing the best combination for your particular application

1392. MECHANICAL AND DIFFUSION PUMP, Water-Cooled.
For 115 volts, 60 Cycles, A.C. **Each, $320.00**

1392A. MECHANICAL AND DIFFUSION PUMP, Air Cooled.
For 115 volts, 60 Cycles, A.C. **Each, $320.00**
For attached Belt Guard, add $15.00 to above prices.

1391. DIFFUSION PUMP, Only, Water Cooled, with Octoil. **Each, $170.00**

1394. DIFFUSION PUMP, Only, Air Cooled, with Octoil. **Each, $170.00**

1393. MOUNTING PARTS.
For mounting No. 1391 or No. 1394 Diffusion Pump on base of mechanical pump. **Set, $3.00**

Chem Ed

EDITORIALLY SPEAKING

Anthropomorphism is a concern that does not keep many chemistry teachers awake at night. It and its companion specter, teleology, haunt the thoughtful biologist more than his chemist counterpart. Nevertheless, total disregard of the thin philosophical ice represented by these two concepts can dump both chemistry teachers and students into the icy waters of nonsense.

Webster defines anthropomorphism as "An interpretation of what is not human or personal in terms of personal characteristics." Teleology is "The fact or character attributed to nature or natural process of being directed toward an end or shaped by a purpose." Atoms and molecules are so thoroughly inanimate that no chemist really regards them anthropomorphically or teleologically. However, the beginning student, philosophically as well as scientifically naïve, can get into real trouble if he takes seriously such a statement as "Sodium reacts with chlorine *because* the chlorine atom *eagerly* takes on the electron that the sodium atom is *so willing* to discard." We have supplied the italics, but the quote is verbatim from a general chemistry text copyrighted in 1939.

It is significant that more recent books carefully avoid this kind of statement. About the closest is such a sentence as, "The sodium atom is not 'aware' of a chlorine atom at an infinite distance." The quotation marks are the authors'. This situation seems to reflect the current attitude of chemistry teachers. A lecture can be brightened greatly by strikingly colorful or unexpected language. In context it often can hammer home a point for a puzzled student, much as any cleverly drawn analogy will. Many a truly great scientist has displayed his equal stature as teacher by such invention. Henry Eyring's "electron claustrophobia," for example, is especially rich in connotation with implications ranging from simple molecular geometry to quantum mechanics.

Anthropomorphic language is less dangerous in a lecture than in a text from which a student studies. However, even in a lecture, the speaker should be sure that audible or implied quotation marks go around his invented atomic or molecular personalities. This is easier to do when describing some thing rather than some process. Perhaps this is because chemical reactions are inherently more complicated than the simple symbolism of equations or even electron dot formulas can convey. Even quotation marks cannot give respectability to the statement, "A reaction obeys Le Chatelier's Principle because it wants to go to equilibrium."

If we return to the first quotation and examine the language, we see that this chemical baby-talk later will be regarded as nonsense by the properly educated student. He may be able to translate *eagerly* into electron affinity by stretching things, but the implication that the sodium is *so willing* (wants) to discard an electron runs into all sorts of difficulties. To tell the story correctly from an enthalpy viewpoint certainly makes justifying "want" difficult. Similarly to blanket free energy-entropy arguments or even the Born-Haber cycle by the simple word "want" would be quite a feat.

Perhaps the sly word that causes the most trouble for the novice is the word "because." Its use with beginners always needs care and amplification to avoid the easy attractiveness of a teleological connotation. The scientist may predict because he has faith in his theory, but the atoms and molecules are not scientists. Put anthropomorphically, the atoms have taken neither Chemistry 101 nor Chemistry 999. If the student is helped to realize clearly that "because" really means a correlation between information about structure and properties, the professor has done his job. Anything short of that is poor teaching. The next generation of educated men and women deserves better.

Significant Structure Theory of Liquids

One of the most elusive properties of nature has been a complete and consistent theory of liquids. Since the formal development of statistical mechanics some thirty years ago, there have been two main approaches to a liquid theory. There is the formal or fundamentalist approach pioneered by Mayer and Kirkwood among others and currently being widely pursued. An alternate method of attack is the model approach. In this method one visualizes a physical picture of a liquid, translates the picture into a mathematical equation, i.e., a partition function, and then computes the thermodynamic and mechanical properties of the liquid. If the model is reasonable and the calculated results agree with the experimentally determined values with sufficient faithfulness, then one assumes that the model is an adequate description of the liquid.

The formal approach provides the aesthetic pleasure of initial rigor, but at some stage during its development, up to the present at any rate, approximations must be introduced either in the form of simplified mathematics or oversimplified intermolecular potentials. In time such difficulties may be overcome. When this does happen, it will constitute a noteworthy advance.

The model approach has several immediate advantages. First of all it gives a clear visual picture of a liquid and thus provides a physical explanation for a variety of phenomena. Second, the mathematical manipulations are greatly simplified, thus reducing the elapsed time between initial interest in the value of some particular property of a specific liquid and a knowledge of the value of this property.

Naïvely, one might say that the choice between the mathematical and model approaches reduces to a choice of the time for making one's approximations. In the model approach the approximations are made at the beginning; in the formal approach they are made at the end.

The theory of liquids to be presented in this paper is a model approach and is analogous to the models customarily used for solids and gases.

We next catalog some of the known properties of the liquid state. As the temperature of a solid is increased, the substance suddenly melts to form a liquid. With a further rise, the density decreases until finally the liquid and vapor phases merge into one fluid-like substance at the critical point. This would indicate that a description of a liquid should reduce to a description of a solid or gas at the respective limits. From X-ray scattering experiments on liquids such as argon (*1*) we gain information of a more detailed nature. As the temperature of a solid increases, the coordination number of nearest neighbors, decreases from 12 in the solid to 10 or 11 in the liquid at the melting point. With rising temperature the coordination number, z, steadily decreases to approximately 4 at about five degrees below the critical temperature and then rises to 6 at the critical point. While the coordination number is decreasing to 4, the distance between nearest neighbors remains almost constant (3.8 Å for argon). Then as z rises to 6 the distance between neighbors increases (to 4.5 Å). Furthermore, the X-ray data indicates that those molecules immediately surrounding a given molecule (i.e., its nearest neighbors) are arranged in an orderly manner. The second and third nearest neighbors are arranged in a somewhat random fashion and beyond that chaos reigns. To say this in another way, a liquid possesses short range order, but a total lack of a long range order.

Excess Volume—Fluidized Vacancies

Now may we reconcile the fact that as the temperature increases the volume increases, yet the average distance between molecules remains fairly constant? A simple way of explaining this is to imagine that some of the molecules are replaced by vacancies. For example, argon expands 12% upon melting. This corresponds to removing about every eighth molecule. This would have two desirable effects. First, it would increase the volume simply by increasing the number of sites at the same time keeping the intermolecular distance more or less constant. And second, when two or more molecules share a vacancy, the lattice structure or orderly arrangement is destroyed so that we no longer have long range order.

Since the introduction of vacancies into a liquid seems to be a simple and satisfactory way of accounting for expansion, constant intermolecular distance, and lack of long range order, we shall now proceed to formulate a partition function which skirts certain difficulties and yet expresses this concept.

The key to the Pandora's box of liquids lies in elucidating the use a liquid makes of the *excess volume*, $V - V_s$, where V is the molar volume of the liquid and V_s is the molar volume of the solid. The liquid apparently utilizes this excess volume in two ways. First of all, if a molecule is rambunctious enough, that is to say if it has sufficient kinetic energy, it will take possession of some of this excess volume by pushing the neighboring molecules out of the way. By doing this it will gain entropy, or speaking in terms of a partition function, it will gain a degeneracy factor. The second use the liquid makes of the excess volume is to allow the molecule to possess translational degrees of freedom. Let us observe some particular molecule in the liquid. At some particular time it will be completely surrounded by other molecules, and so it will be vibrating about some point in space with about the same fundamental

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

vibration frequency that it would have in the solid. When it is oscillating this way, we say that it is behaving in a *solid*-like manner. It then acquires some energy (by collisions with one or more of its neighbors) and transfers this energy into one of its vibrational modes of motion. The molecule then vibrates so hard in some direction that it pushes the neighboring molecules aside and takes possession of an additional position. In this process of moving to a new position external vibrational degrees of freedom are converted into translational degree of freedom. When a liquid molecule possesses translational degrees of freedom, we say it is acting in a *gas*-like manner. One naturally asks, how are the total number of degrees of freedom to be partitioned between solid- and gas-like degrees of freedom?

Before answering this question we should make a few comments about the excess volume. There are no stationary solid-like vacancies in a liquid. Light scattering experiments rule out such inhomogeneities in density. Furthermore, it is well known that liquids superheat when they are heated in vessels so clean that bubbles do not form on the walls. Thus it is clear that pure liquids have no "holes" large enough to act as nuclei for bubble formation. Also the structure of a liquid is very unstable with molecules rapidly shifting their position. Due to this rapid and irregular motion of the molecules, care must be exercised in speaking of a lattice or empty lattice site. Nevertheless, there is an excess volume, $V - V_s$, in the liquid, and this excess volume can be acquired by a molecule by pushing out its competitors. Only when a molecule has enough energy to push the neighboring molecules aside, however, does it become appropriate to speak of a hole or empty lattice site coming into existence. We call these holes *fluidized vacancies* or sometimes simply holes or vacancies. We wish to make clear, however, that these holes are very different from the locked-in almost static vacancies found in solids. The analogy between holes in a liquid and positions in an electron sea is very good. It is immaterial whether we think of molecules or electrons moving in one direction or holes or positrons moving in the other. Now certainly a hole by itself has no properties; but when a hole is surrounded by molecules, it becomes convenient to think of the hole as possessing properties. By moving into the hole, the surrounding molecules confer gas-like properties on the hole. It is simply a question of convenience whether we speak of the molecules possessing translational degrees of freedom or of the holes behaving as gas-like molecules; both descriptions refer to the same phenomenon. Likewise the term solid-like molecules does not imply that there are microcrystalline regions in the liquid. We simply mean that for short periods of time the motion of a molecule will be oscillatory. During other periods of time the motion of a molecule is translational. It reduces to a question of semantics whether we refer to these motions as solid- and gas-like or vibrational and translational.

Returning to the division of the total number of degrees of freedom, we assume that the excess in volume between the solid and liquid, to a sufficient degree of approximation, can be measured in terms of holes of molecular size. In one mole of liquid there are $(V - V_s)/V_s$ moles of vacancies per mole of molecules. The fraction of occupied positions adjacent to a vacancy is, assuming complete randomness, V_s/V. Now as we said before, a hole surrounded by vacancies has no properties; it is the molecules around a hole which confer properties on the vacancy. Thus if we multiply the number of holes, $(V - V_s)/V_s$, by the probability of molecules occupying positions around the hole, V_s/V, we obtain $(V - V_s)/V$ for the fraction of vacancies endowed with gas-like properties. The remaining fraction of a mole, V_s/V, may be thought of as associated with solid-like molecules.

Accordingly, the heat capacity at constant volume, C_v, of a mole of argon should be given closely by the sum of the contributions from V_s/V moles of solid and $(V - V_s)/V$ moles of gas. Thus:

$$C_v = 6 \cdot \frac{V_s}{V} + 3 \cdot \frac{V - V_s}{V} \qquad (1)$$

This expression was first suggested by Walter and Eyring (*2*). Its validity is tested in Figure 1. The results are sufficiently encouraging to cause us to develop the fluidized vacancy theory.

Figure 1. Heat capacity at constant volume for liquid argon. The solid curve represents equation (1), and the circles represent the experimental data.

The concept of fluidized vacancies has another advantage: it explains quite nicely the law of rectilinear diameters. This law states that the average density of a liquid and its vapor is nearly independent of temperature decreasing slowly in linear fashion as the temperature increases from the melting to the critical point. If a molecule is transferred from the liquid to the vapor without displacing the neighbors, i.e., leaving a vacancy, all bonds to neighbors are broken. In ordinary vaporization only half this energy is required since again all bonds to its neighbors are broken, but each bond joins two molecules and therefore only half the energy of a bond should be charged against each molecule. Thus the energy to make a vacancy just equals the heat of vaporization. Further, a vacancy in the liquid moves about as freely as does a molecule in the vapor. Thus the entropies of a hole and of a gas molecule should be about equal. Now since the vacancies and the vapor molecules have the same energy and entropy, it is to be expected that there will be as many vacancies per unit volume of liquid as there are molecules per unit volume of vapor. Thus the sum of the densities of the liquid and vapor will be constant except for the slight lattice expansion of the liquid causing the density of the liquid to de-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

crease slightly with temperature. Consequently, the mean density of liquid and vapor should decrease slightly with temperature (*3*).

A cardinal principle in significant structure theory is that molecular structures in the vapor are mirrored in the liquid as analogous structures made out of vacancies. Thus individual molecules translating in the vapor are mirrored as vacancies translating in the liquid. Rotating molecules are mirrored as rotating vacancies. Association of vapor molecules is matched in the liquid by association of the corresponding vacancies which translate and rotate like their molecular counterparts. This principle has been applied and verified for ordinary liquids, metals, and molten salts.

Formulation of the Partition Function

We return to the formulation of the partition function. If a molecule is to take possession of one of the fluid vacancies, it must push the neighboring molecules aside. When it does have the required energy, the additional sites become available to a molecule and there is a degeneracy factor equal to the number of sites available. The number of additional sites will be equal to the number of neighboring position, n_h, which a rambunctious molecule can occupy multiplied by the probability that the molecule has enough energy, ϵ, to move into one of these sites. Thus the number of additional sites is:

$$n_h e^{-\epsilon/kT}$$

Therefore, the total number of positions available to a given molecule is

$$1 + n_h e^{-\epsilon/kT} \tag{2}$$

If we now assume that the vibrational degrees of freedom, i.e., the solid-like molecules, are adequately represented by an Einstein oscillator (which for temperatures corresponding to the liquid region is a good approximation), we can write for the partition function, f, for a monatomic liquid such as argon the expression:

$$f = \left\{\frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^3} \cdot (1 + n_h e^{-\epsilon/kT})\right\}^{N(V_s/V)} \cdot \left\{\frac{(2\pi mkT)^{3/2}}{h^3}(V - V_s)\right\}^{N(V-V_s)/V} \cdot \left\{\left(\frac{N(V - V_s)}{V}\right)!\right\}^{-1} \tag{3}$$

The first set of brackets represents the solid-like portion of the partition function. The remaining portion is the gas-like part. In the partition function for a nonlocalized independent system the number of complexions is overcounted due to the indistinguishability of the particles. Thus we must divide by the number of particles factorial. This explains the factorial term, $[N(V - V_s)/V]!$, at the end of the equation (3). Using Sterling's approximation, $x! = (x/e)^x$, equation (3) becomes

$$f = \left\{\frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^3}(1 + n_h e^{-\epsilon/RT})\right\}^{N(V_s/V)} \cdot \left\{\frac{(2\pi mkT)^{3/2}}{h^3} \cdot \frac{eV}{N}\right\}^{N(V-V_s)/V} \tag{4}$$

where θ is the Einstein characteristic temperature. Note that when $V = V_s$ the exponent of the second set of brackets goes to zero leaving the partition function of a solid since $n_h e^{-\epsilon/RT}$ also goes to zero. When V is much larger than V_s, the first set of brackets effectively becomes unity and we are left with the partition function of a gas. Accordingly, this partition function has the correct asymptotic behavior. Within the solid-like portion of the partition function the factor $e^{E_s/RT}/(1 - e^{-\theta/T})^3$ occurs. This is the Einstein partition function for the external vibrations of the atom. E_s is the sublimation energy, and so the reference energy in this theory is for the atoms in their lattice framework rather than the separated atoms.

The quantity $(1 + n_h e^{-\epsilon/RT})$ is the geometrical degeneracy factor, and it is a direct result of a molecule appropriating excess volume. Accordingly, we expect n_h to be proportional to the excess volume,

$$n_h = n(V - V_s)/V_s \tag{5}$$

while ϵ should be inversely proportional to the excess volume and directly proportional to the energy of sublimation of the solid. Thus

$$\epsilon = \frac{aE_sV_s}{V - V_s} \tag{6}$$

We next require values for the proportionality factors n and a. These may be evaluated by calculating n_h and ϵ near the melting point where the liquid still approximates a solid lattice. Thus near the melting point the fraction of the neighboring positions, Z, which are empty and therefore available for occupancy is

$$Z \cdot \left(\frac{V - V_s}{V}\right) = \left(Z\frac{V_s}{V}\right) \cdot \frac{V - V_s}{V_s} = n\frac{V - V_s}{V_s} \tag{7}$$

Hence

$$n = \frac{ZV_s}{V} = 12 \cdot \frac{1}{1.12} = 10.7 \tag{8}$$

is to be compared with the value 10.8 required to fit experimental data. These added positions should be available without extra energy to a neighboring molecule. However, in melting, the other neighbors to the position have gained the kinetic energy of melting by spreading into the vacancies. According to the virial theorem the kinetic energy of melting is half the total energy of melting, E_m. Thus at, or very near the melting point

$$\frac{aE_s \cdot V_s}{V - V_s} = \frac{n - 1}{Z} \cdot \frac{1}{2}E_m \simeq \frac{n - 1}{Z} \cdot \frac{1}{2}\frac{V - V_s}{V}E_s \tag{9}$$

Hence

$$a = \frac{n - 1}{Z} \cdot \frac{1}{2}\frac{V - V_s}{V}\frac{V - V_s}{V_s} = 0.0052 \tag{10}$$

This value for a is to be compared with the value 0.00534 which is chosen to fit experimental data. The fraction $(n - 1)/Z$ results from the fact that a molecule expanding into the vacancy acquires $1/Z$ of its kinetic energy of melting and there are only $n - 1$ molecules to compete with the molecule in question. Our model thus fixes all the parameters in liquid theory except those which are properties of the solid.

An essential point in any model of the liquid is that it explains the utilization of excess volume introduced by melting. A model which omits this explanation is either a superheated solid or chilled vapor theory and not really a liquid theory at all.

Obviously, equation (9) is only approximate, but it does give a good estimate for the value of a. The error in the value of a is due to two causes. The

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

quantity $E_s (V - V_s)/V$ gives a value for the heat of fusion which is about 10% too low. On the other hand the value $^1/_2$ obtained from the virial theorem for the needed kinetic energy is undoubtedly only approximate. A molecule in the liquid state is apt to lower its potential energy as it is pushed out of the excess volume. Therefore, the factor $^1/_2$ in equation (9) should be smaller. The errors in these two factors probably about compensate each other.

The theory also leads to a radial distribution function. Knowing the molar volume of the solid and the type of packing in the solid phase, we can compute the size of the molecules. If we now arrange these molecules in the volume V in the most random way possible (in obtaining the fraction of solid- and gas-like molecules, we have assumed complete randomness), we can compute a radial distribution function. Due to the fact that the molecules are not rigid spheres, but rather are elastic molecules, and since there is a distribution of kinetic energies, the peaks of the distribution function will be smeared-out, as is observed experimentally.

Using equations (5) and (6), equation (4) can be rewritten

$$f = \left\{ \frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^3} \cdot \left(1 + n \frac{V - V_s}{V_s} e^{-\frac{aE_sV_s}{RT(V-V_s)}} \right) \right\}^{N(V_s/V)} \cdot \left\{ \frac{(2\pi mkT)^{3/2}}{h^3} \cdot \frac{eV}{N} \right\}^{N(V-V_s)/V} \quad (11)$$

This is the form in which the partition function for Significant Structure theory is most frequently written. Equation (11) is for liquids composed of monatomic molecules. Naturally for systems which possess internal vibrations and rotations, the appropriate expressions must be added to the solid- and gas-like portions of the partition function.

Calculation of Thermodynamic Properties

With the basic partition function given in equation (11) we are in an excellent position to calculate thermodynamic properties from the melting point to the critical point for a wide variety of substances ranging from such near-ideal liquids as argon to nonideal systems such as water. The relation between the Helmholtz free energy, A, and the partition function is

$$A = -kT \ln f \quad (12)$$

Since we now have A as a function of V and T, we can calculate all other thermodynamic properties from

$$S = -\left(\frac{\partial A}{\partial T}\right)$$

$$E = -T^2 \left[\frac{\partial (A/T)}{\partial T}\right]_v$$

$$P = -\left(\frac{\partial A}{\partial V}\right)_T \quad (13)$$

$$C_v = T \cdot \left(\frac{\partial S}{\partial T}\right)_v = -T\left(\frac{\partial^2 A}{\partial T^2}\right)_v$$

$$\alpha = \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P = -\left(\frac{\partial P}{\partial T}\right)_v \Big/ \left[V \cdot \left(\frac{\partial P}{\partial V}\right)_T\right]$$

and similar expressions for the remaining thermodynamic properties.

Inert Gases (4)

For the liquid inert gases we use the partition function given in equation (11). E_s, θ, and V_s are taken from the properties of the solid phase; n is determined from equation (8) and a is estimated from equation (10). Some of the results are summarized in Table 1. It will be noted that the calculated critical pressure is in all cases too high. Inspection of equation (11) produces a possible explanation for this. As the critical point is approached, clustering becomes important. That is, concentrations of the dimer and trimer in the vapor phase become significant and thus should be included in the partition function. These clusters have the effect of decreasing the pressure. Equation (11) only includes monomers in the gas-like portion of the partition function. Presumably, inclusion of a dimer term would improve the results.

Diatomic Liquids

Significant Structure theory has been applied to a number of diatomic liquids: nitrogen (*4*), chlorine (*5*), fluorine, bromine (*6*), iodine (*6*), and also hydrogen (*7*) which requires the use of quantum statistics. The theory is presently being applied to liquid oxygen. Let us examine the application of the theory to chlorine for which the results are typical.

The unusually high entropy of fusion and the absence of transition peaks in the heat capacity curve for solid chlorine indicate that the chlorine molecule does not rotate freely in the solid state. Also the density data on liquid chlorine suggest that rotation is hindered in the liquid state. To avoid complicating the partition function by considering libration-type degrees of freedom, the six degrees of freedom in the solid-like portion of the partition function are assigned to a five degree Einstein oscillator and one internal vibration. Free rotation was assumed in the gas-like portion of the partition function. The partition function for liquid chlorine, then, is:

$$f_{Cl_2} = \left\{ \frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^5} \cdot \frac{1}{(1 - e^{-h\nu/kT})} \cdot (1 + n_h e^{-aE_sV_s/RT(V_s - V)}) \right\}^{N(V_s/V)} \cdot \left\{ \frac{(2\pi mkT)^{3/2}}{h^3} \cdot \frac{eV}{N} \cdot \frac{1}{(1 - e^{-h\nu/kT})} \cdot \frac{8\pi^2 IkT}{2h^2} \right\}^{N(V-V_s)/V} \quad (14)$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Figures 2 and 3 compare some of the calculated and observed properties. The critical temperature is about 11% too high, the critical volume about 6% too high, and the critical pressure is too large by 38%. The results for chlorine are typical of the results obtained for many other liquids: from the melting point to the boiling point the agreement with experiment is very good; above the boiling point deviations occur so that T_c and V_c are 5–10% too high and P_c is 30–50% too large.

Figure 2. Vapor pressure versus temperature for liquid chlorine.

Figure 3. Molar volume versus temperature for liquid chlorine.

Organic Liquids

The theory has been applied to a number of organic liquids ranging from such simple hydrocarbons as methane, ethane, and benzene (*4*) to the halocarbons, carbon tetrachloride and carbon tetrafluoride (*8*). The experimental heat capacity curves for both CH_4 and CCl_4 indicates that the molecules rotate in the solid state. We therefore assume that they rotate in the liquid state. The partition function for liquid CH_4 or CCl_4 then is

$$f = \left\{\frac{e^{E_s/RT}}{(1-e^{-\theta/T})^3}\left(1 + n\,\frac{V-V_s}{V_s}\,e^{-aE_sV_s/RT(V-V_s)}\right)\right\}^{N(V_s/V)} \cdot \left\{\frac{(2\pi mkT)^{3/2}}{h^3}\cdot\frac{eV}{N}\right\}^{N(V-V_s)/V} \cdot \left\{\prod_{i=1}\frac{1}{(1-e^{-h\nu_i/kT}}\cdot\frac{(8\pi^2kT)^{3/2}\cdot(\pi ABC)^{1/2}}{12\cdot h^3}\right\} \quad (15)$$

A, B, and C are the principal moments of inertia and the factor 12 is the symmetry number for molecules having the configuration of a CH_4 molecule. Since the partition functions for the internal vibrations and the rotations occur in both portions of the partition function, we have factored them out for convenience. Some of the results for methane are given in Table 2.

Molten Metals (9)

Since the conducting (outer) electrons of a metal are spead out over the positive ions, only vacancies for the ions need appear in the liquid. In general, ions are only about a third the size of atoms, therefore the vacancies are also smaller. Thus when metals melt, they expand only 3 or 4%, that is, about a third as much as a normal liquid. However, the entropy of melting is almost the same as that of a normal liquid, so it follows that n must have a value three times that of a normal liquid. In the vapor above a molten metal appreciable concentrations of the dimer species exist. Arguments similar to those used in explaining the law of rectilinear diameters lead one to conclude that the vacancies in the liquid are also paired. Due to the relatively high dimer concentration in the vapor a dimer term has been included in the gas-like portion of the partition function for molten metals.

$$= \left\{\frac{e^{E_s/RT}}{(1-e^{-\theta/T})^3}\left(1 + n\,\frac{V-V_s}{V_s}\,e^{-aE_sV_s/RT(V-V_s)}\right)\right\}^{N(V_s/V)} \cdot \left\{\left(f_1\cdot\frac{eV}{N}\right)^2 + \left(f_2\cdot\frac{eV}{N/2}\right)\right\}^{N/2/(V-V_s)/V} \quad (16)$$

where

$$f_1 = \frac{(2\pi m_1kT)^{3/2}}{h^3}$$

$$f_2 = \frac{(2\pi m_2kT)^{3/2}}{h^3}\cdot\frac{8\pi^2IkT}{2h^2}\cdot\frac{e^{D/RT}-1}{1-e^{-h\nu/kT}}$$

and m_1, m_2, I, D, and ν are the masses of the monatomic and diatomic metal atoms, the moment of inertia, the dissociation energy, and the ground state vibrational frequency of the dimer. As $T \rightarrow T_c$, the electrons are no longer smeared-out over the positive ions, and the atoms no longer behave as if they were ions. Thus the value of n must now be near to that of a normal liquid. The partition function in equation (16) has been used to calculate properties for liquid sodium, mercury, copper, and lead. Some typical results are

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

given in Figure 4, which plots molar volume versus temperature for liquid mercury over a four hundred degree temperature span. At 600°K it is approximately 3% too small.

Figure 4. Molar volume versus temperature for liquid mercury.

Fused Salts (10)

The observed percentage change in volume for argon upon melting is 12%. For molten salt such as NaCl the per cent expansion is approximately twice that of argon. The entropy of melting comes from the randomness introduced by the excess volume. Since positive ions can occupy only half of the fluid vacancies while negative ions can occupy the other half, it should require twice the per cent expansion to obtain the same entropy increase for each kind of ion. This is in accord with the experimental observations. The fact that only half the excess volume provides vacancies for each kind of ion means the factor n in the degeneracy should only be about half as large for salts as it is for argon. The partition function for a mole of alkali halide molecules is

$$f = \left\{ \frac{e^{(E_s/2RT)}\,(V/V_s)^{1/3}}{(1-e^{-\theta/T})^3} \left(1 + n_h e^{(-a'E_s/n_h RT)}\,(V/V_s)^{1/3}\right) \right\}^{2N(V_s/V)} \cdot \left\{ \frac{(2\pi mkT)^{3/2}}{h^3} \cdot \frac{eV}{N} \cdot \frac{8\pi^2 IkT}{h^2} \cdot \frac{1}{(1-e^{-h\nu/kT})} \right\}^{N(V-V_s)/V} \quad (17)$$

the solid-like portion of the partition function is raised to the $2N\ V_s/V$ power because a mole of alkali halide contains $2N$ particles. The alkali metal ions and the halide ions are in the same environment so a common Einstein temperature is used for both. E_s/N is the sublimation energy per molecule. The E_s required in the partition function is the sublimation energy per ion so we must divide by two. To account for the long-range nature of the coulombic interionic potential the sublimation energy must be altered. For liquid argon (see eq. (11)) the energy falls off as $E_s\ V_s/V$, that is inversely as the volume which was what van der Waals suggested for gases long ago. This is not true for the molten salts, however, since in one of the three dimensions a Na^+ and a Cl^- cling together, and so there is expansion only in the other two directions. Therefore, the energy should decrease about as $1/V^{2/3}$; thus in the partition function we multiply E_s by $(V/V_s)^{1/3}$. The gas-like portion of the partition function is composed of molecules whose moments of inertia and ground state vibrational frequencies are assumed to be the same as for the vapor phase. A summary of the results is given in Table 3. The agreement with the observed data is good. Recent experimental work has indicated that vapors of the alkali halides are strongly associated to four and six atom complexes. Inclusion of these terms in the partition function should improve the results.

Figure 5. Vapor pressure of liquid para hydrogen, hydrogen deuteride and ortho deuterium.

Liquid Hydrogen (7)

The theory has been applied with excellent results to liquid hydrogen, deuterium, and hydrogen deuteride. It provides an interesting test for this approach to liquids since changes in the concentrations of ortho and para hydrogen cause slight changes in the thermodynamic properties. Because these liquids exist at extremely low temperatures a Debye partition function is used for the solid-like degrees of freedom and equation (7) is used for n_h. The gas-like molecules are treated as a slightly degenerate gas which obeys Bose-Einstein statistics for the cases of hydrogen and deuterium and Fermi-Dirac statistics for the

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

case of hydrogen deuteride. Henderson thus obtained the following partition function

$$f = \left\{\frac{e^{E_s/RT}}{f_D}(1 + n_A e^{-aE_s V_s/RT(V-V_s)}) \cdot f_r\right\}^{N(V_s/V)} \cdot \left\{e^{(1-\ln y \pm y/2^{3/2})} \cdot f_r\right\}^{N(V-V_s)/V} \quad (18)$$

where f_D is the Debye partition, f_r is the rotational partition function and depends upon the species, and y is related to the translational partition function. The reader is referred to the original paper for more details on the partition function, since it is inherently complex. Table 4 lists some calculated and observed properties at the melting, boiling, and critical point. Figure 5 shows the vapor pressure curves versus temperature for several species.

Dense Liquids and Gases (11)

The theory as described above works very well for normal temperatures and pressures. A few simple corrections, which are natural consequences of the model, extend the useful range of the theory to very high pressures and temperatures with highly satisfactory results.

In using an Einstein oscillator in the solid-like portion of the partition function it was tacitly assumed that $l\,\theta \gg T$, where l is the vibrational quantum number. The exact partition function of a one dimensional harmonic oscillator terminating at the l-th level is given by

$$\sum_{i=0}^{l-1} e^{-i\theta/T} = \frac{1 - e^{-l\theta/T}}{1 - e^{-\theta/T}} \quad (19)$$

and l is determined by the relation $l\,\theta \simeq E_s/3R$. The usual Einstein partition function is obtained when $l\,\theta \gg T$. This condition, $l\,\theta \gg T$, however, does not hold at high temperatures for substances with a low E_s (i.e., low molecular weight substances such as argon and neon). When this condition is no longer satisfied, the one dimensional oscillator becomes a one dimensional gas with one translational degree of freedom:

$$e^{-l\theta/T}\frac{(2\pi mkT)^{1/2}}{h} \cdot \nu_f^{1/3} \quad (20)$$

where ν_f is the molar free volume in the solid. Since at high temperatures molecules act like hard spheres, ν_f may be represented by

$$\nu_f = [(V_s/N)^{1/3} - (b/4N)^{1/3}]^3 \quad (21)$$

where b is the van der Waals constant and $b/4N$ is the net molecular volume. We, therefore, replace the simple Einstein partition function in equation (11) by

$$e^{E_s/RT}\left\{\frac{1 - e^{-l\theta/T}}{1 - e^{-\theta/T}} + e^{-l\theta/T} \cdot \frac{(2\pi mkT)^{1/2}}{h} \cdot \nu_f^{1/3}\right\} \quad (22)$$

When $l\,\theta \gg T$, equation (22) reduces to the Einstein partition function in equation (11); and when $T \gg l\,\theta$, it reduces to a translational partition function.

The equation of state obtained from equation (11) modified by means of equation (22) is

$$P = \frac{RT}{V_s x^2}\left[-\sigma_1 - \sigma_2 + x \cdot \left(\frac{2\sigma_2}{2x}\right)_T + \gamma + x - 1\right] \quad (23)$$

where

$$x = V/V_s$$

and

$$\sigma_1 = E_s/RT + 3\ln\left\{\frac{1 - e^{-l\theta/T}}{1 - e^{-\theta/T}} + e^{-l\theta/T} \cdot \frac{(2\pi mkT)^{1/2}}{h} \cdot \nu_f^{1/3}\right\}$$

$$\sigma_2 = \ln\{1 + n(x-1)e^{-aE_s/RT(x-1)}\} \quad (24)$$

$$\gamma = \ln\left\{\frac{(2\pi mkT)^{3/2}}{h^3} \cdot \frac{eV}{N}\right\}$$

In addition to the quantum effect mentioned above, the pressure effect on V_s must also be considered. Thus

$$V_s = V_s(1 - \beta\Delta P) \quad (25)$$

β is the solid compressibility and ΔP is the excess pressure above a standard pressure, say the vapor pressure at the melting point. Since β is rather small, 10^{-5} to 10^{-7} atm^{-1}, equation (25) reduces to V_s if ΔP is small. For argon, as an example, the pressure effect is negligible if ΔP is less than 500 atmospheres.

From equation (23) the second virial coefficient may be determined:

$$B(T) = V_s(\gamma - \sigma_1 - \ln n) \quad (26)$$

and compared with experiment. Some results for nitrogen are shown in Figure 6. Figure 7 shows the compressibility factor, PV/RT, as a function of density for argon at 150°C. The values obtained by Kirkwood and Hirschfelder are also shown.

As noted earlier, the partition function used in this theory reduces to a solid partition function when $V = V_s$ and to a gaseous partition function when $V \gg V_s$. Thus it is reasonable to expect that this partition function will also represent the surface layer, if the density gradient is taken into account. For a simple close packed liquid such as argon, it is supposed that the molecules on the surface will orient such that each molecule will tend to have six neighbors in the same layer, three neighbors below and three above. Only E_s, the bulk energy of sublimation, should be appreciably different for a surface and a bulk molecules. The energy E_{s_i} of a molecule in the ith surface layer is given by the relationship.

$$E_{s_i} = E_s\left(\frac{6}{12}\frac{\rho_i}{\rho_i} + \frac{3}{12}\frac{\rho_{i+1}}{\rho_i} + \frac{3}{12}\frac{\rho_{i-1}}{\rho_i}\right) \tag{27}$$

Here ρ_i is the density of the ith layer and the subscript increases with depth in the liquid. If $\rho_{i+1} > \rho_i$, then more molecules are in the ith + 1 layer with respect to the ith layer. That is, the molecules in the ith + 1 layer are bound more tightly, or $|E_{s_{i+1}}| > |E_{s_i}|$. When i is the top liquid layer and $(i - 1)$ the first gas layer, we can write

$$\rho_{i-1}/\rho_i = e[-(E_s/2RT)(1 - T/T_c)] \tag{28}$$

This corresponds to a molecule in the top liquid layer possessing six nearest neighbors in the same plane, three in the neighboring liquid plane, but none in the gas layer at low temperatures. A molecule in the first gas layer, on the other hand, has only the three neighbors in the first liquid layer and no neighbors in the same gas layer or in the gas layer above. Thus, the extra binding energy of a molecule in the first liquid layer over one in the first gas layer corresponds to six more neighbors out of a possible twelve or an extra binding energy of $E_s/2$. In keeping with this result the exponent of equation (28) reduces to $E_s/2RT$ at low temperatures and vanishes at $T = T_c$, as it must since the densities become equal at the critical temperature.

The Gibbs free energy per mole, $G_i = A_i + PV_i$, for each surface layer may now be calculated by means of equations (27) and (28) by using an iterative process to determine the ρ_i's. The surface tension, γ, may be calculated from the relationship

$$\gamma = \sum_i \Delta G_i \cdot \frac{0.9165}{V_i}\left(\frac{V_s}{N}\right)^{1/3} \tag{29}$$

where ΔG_i is the difference in free energy of one of the surface layers and the bulk liquid. The remaining factor is the volume of a layer of surface lattice one cm² in area assuming a face centered cubic lattice. Other types of packing would give a different factor.

Surface tensions have been calculated for argon, nitrogen, and methane at several temperatures. The results are given in Table 5. The columns labeled 1st, 2nd, and 3rd are the per cent contributions to the

Transport Properties (9)

Significant Structure theory includes a general theory of transport properties implicitly. It is interesting to note that when the liquid and solid phases have the same free energy, as they do at the melting point, their viscosities differ; i.e., different shear stresses are needed to maintain unit velocity gradients. This difference in viscosity must arise from the change in structure. Although they melt at different temperatures, normal liquids have about the same viscosity (~2 centipoises) at their melting point. Long ago Batschinski (*14*) noted that the reciprocal of the viscosity, the fluidity, is proportional to the volume of the liquid minus a volume very close to that of the solid, i.e., what we call the excess volume. This observation is a natural consequence of the significant structure approach to liquids.

Consider the shear surface between two layers of molecules. Shearing occurs as molecules on either side of the shear plane move into those fluidized vacancies which will relieve the accumulated stress. Obviously, this motion can only occur during the time a vacancy is available for occupancy. The probability of such a vacancy being at a particular point will be proportional to the number of vacancies, $V - V_s$. Thus the rate of shear, the fluidity, is proportional to this excess volume. This explains Batschinski's results. Moreover, most liquids have about the same concentration of vacancies at their melting points. Since the rate of jumping is nearly the same for each liquid at its T_m, we would expect liquids to have the same visocity at their very different melting points. Most liquids do.

Since there are different types of degrees of freedom (solid-like and gas-like) in the liquid, they both must be taken into account in calculating the viscosity. The shear plane lies between two molecular layers. If a fraction, X_s, of the shear plane is covered by solid-like molecules and the remaining fraction, X_g, by gas-like molecules, then the viscosity, η, which is the ratio of shear stress, f, to rate of strain, $\dot{s}$, is given by

$$\eta = \frac{f}{\dot{s}} = \frac{X_s f_s + X_g f_g}{\dot{s}} = X_s\eta_s + X_g\eta_g = \frac{V_s}{V}\eta_s + \frac{V - V_s}{V}\eta_g \tag{31}$$

Kinetic theory considerations lead us to

$$\eta_g = \frac{2}{3\pi^2 d^2}(\pi mkT)^{1/2} \tag{32}$$

where d is the effective molecular diameter, for the gas-like viscosity. η_s may be calculated by means of reaction rate theory in the following manner.

If K_i is the frequency of a molecule jumping into the ith neighboring empty lattice site when the shear stress, f, is zero, then, when f is not zero, the work helping the molecule to move forward is the force $f\lambda_2\lambda_3$ (where λ_2 and λ_3 represent intermolecular distances in the shear plane) multiplied by the distance the molecule has jumped, $\lambda \cos \theta_i$. Thus the rate of jumping into the ith site is

$$K_i e^{(f\lambda_2\lambda_3\lambda \cos\theta_i/2kT)} \tag{33}$$

The factor 2 is inserted since it is assumed that the top of the potential barrier is halfway between the two equilibrium positions. η_s may then be written

$$\eta_s = \frac{f}{\dot{s}} = f \Big/ \left\{\sum_i K_i \frac{X \cos\theta_i}{\lambda_1} e^{(f\lambda_2\lambda_3\lambda \cos\theta_i/2kT)}\right\} \tag{34}$$

where λ_1, is the distance between the two molecular shearing planes. Expanding the exponential, we obtain

$$\eta_s = f \Big/ \left\{\frac{\lambda}{\lambda_1}\sum_i K_i \left(\cos\theta_i + \frac{f\lambda_2\lambda_3\lambda \cos^2\theta_i}{2kT}\right)\right\} \tag{35}$$

Since the sites are randomly distributed over the solid angle, we may average $\cos\theta_i$ (which becomes zero) and $\cos^2\theta_i$ (which becomes 1/3):

$$\eta_s = \frac{1}{\sum_i k_i} \cdot \frac{\lambda_1}{\lambda^2\lambda_2\lambda_3} \cdot 6kT \tag{36}$$

Now according to this liquid theory a molecule can jump into any of the neighboring $n(V - V_s)/V_s$ vacancies, and so from absolute reaction rate theory we have

$$\sum_i k_i = \kappa \cdot \eta \frac{V - V_s}{V_s} \cdot \frac{kT}{h} \cdot \frac{F^{\ddagger}}{F} e^{-\epsilon_0/RT} \tag{37}$$

where F and $F^{\ddagger}$ are the partition functions for the molecule in the initial and activated states, and $\epsilon_0 = (a'E_s/RT)(V_s/V - V_s)$ is the activation energy. F and $F^{\ddagger}$ are given by

$$F = \frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^3} \cdot [1 + n_h e^{-\epsilon/RT}]$$

$$F^{\ddagger} = \frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^2} \cdot [1 + n_h e^{-\epsilon/RT}] \tag{38}$$

taking $\lambda^2\lambda_2\lambda_3/\lambda_1 = V_s/N$ and substituting equations (37) and (38) into (36), we obtain

$$\eta_s = \frac{Nh}{V} \cdot \frac{1}{1 - e^{-\theta/T}} \cdot \frac{6}{\kappa n} \frac{V_s}{V - V_s} e^{a\, E_s V_s/RT(V - V_s)} \tag{39}$$

Substitution of equations (39) and (32) into (31) then yields an expression for the viscosity.

The self-diffusion coefficient, D, may be calculated from the relationship

$$D = \frac{kT}{\zeta(V_s/N)^{1/3} \cdot \eta} \tag{40}$$

Current Investigations

At this time we are applying significant structure theory to water, oxygen, and binary mixtures. We are also doing some further work on molten metals. The results of these investigations will appear in the near future. In the article we give the reader a brief indication as to how we are proceeding on these different liquids.

Binary Mixtures

A most exciting problem currently being considered is binary mixtures. If we can successfully apply the theory to mixtures, then a whole new panorama of problems is brought into view. Consider the reaction

$$aA + bB \rightleftharpoons cC + dD$$

One can show that the net rate, r, of this reaction is

$$r = \kappa \frac{kT}{h} F^{\ddagger} (\lambda_A{}^a \lambda_B{}^b - \lambda_C{}^c \lambda_D{}^d)$$

where κ is the transmission coefficient and $F^{\ddagger}$ is the partition function of the activated complex. The λ's are the absolute activities of the respective species and must be obtained from the liquid theory. Thus, if we are able to compute the activities, we will be able to calculate reaction rates and solubilities.

The partition function we are using for binary mixtures is the following

$$f = \frac{(N_1 + N_2)!}{N_1!\, N_2!} \cdot f_1 \cdot f_2 \cdot [(1 + n_h e^{-\epsilon/RT}\, e^{E_s/RT}]^{N(V_s/V)}$$

where

$$f_i = \left[\frac{1}{(1 - e^{-\theta_i/T})^3}\right]^{N_i(V_s/V)} \cdot \left[pf_{tr} \cdot \frac{eV}{N_i}\right]^{N_i(V - V_s)/V}$$

The factorial term is the usual mixing factor which arises from assuming random mixing of the two different species. f_1 and f_2 are the solid- and gas-like portions of the partition functions for the respective species. The main problem with mixtures is to determine how the parameters E_s, V_s, n, and a vary with concentration. Many years ago van der Waals suggested that the energy and volume should vary in the following way:

$$E_s = X_1{}^2 E_{s_1} + 2X_1X_2(E_{s_1}E_{s_2})^{1/2} + X_2{}^2 E_{s_2}$$

$$V_s = X_1 V_{s_1} + X_2 V_{s_2}$$

where X_1 and X_2 are the respective mole fractions, and the E_s's and V_s's are the parameters for the pure components. It is wishful thinking to assume that these equations will work for liquids. They are much more applicable to gases. Averaging formulas developed by Prigogine (*13*) seem more promising. We are presently developing procedures to determine the parameters as functions of concentration.

Water

An interesting problem is presented by water due to the strong hydrogen bonding and the presence of different species. We assume that water is composed primarily of two species: "structured" water molecules which are bound in a rigid lattice and thus do not rotate and "unstructured" water molecules which are assumed to be freely rotating. At low temperatures the structural water molecules are the predominant species. As the temperature increases, more and more molecules begin to rotate until several hundred degrees above the boiling point they are all freely rotating. The ratio of the two species is controlled by an equilibrium constant. The partition function is

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$f = f_s^N(V_s/V) \cdot f_g^{(N/2)}(V - V_s/V)$$

where

$$f_s = \frac{e^{E_s/RT}}{(1 - e^{-\theta/T})^3} \cdot [1 + n_h e^{-\epsilon/RT}] \cdot pf_{\text{vib}} \cdot \left[\frac{1 - e^{-E_0/RT}}{(1 - e^{-\theta/T})^3} + e^{-E_0/RT} \cdot pf_{\text{rot}}\right]$$

$$f_g = \left[pf_{\text{tr}} \cdot \frac{eV}{N} \cdot pf_{\text{vib}} \cdot pf_{\text{rot}}\right]^2 + pf_{\text{tr}_d} \cdot \frac{eV}{N/2} \cdot \frac{8\pi^2 IkT}{2h^2} \cdot pf_{\text{vib}}^2 \cdot pf_{\text{rot}}^2 \cdot \frac{e^{D/RT} - 1}{1 - e^{-h\nu/kT}}$$

$$E_s = \frac{KE_{s_1} + E_{s_2}}{1 + K}$$

$$V_s = \frac{KV_{s_1} + V_{s_2}}{1 + K}$$

At low temperatures f_s reduces to a partition function for the structured water molecules which are treated as 6-degree Einstein oscillators. At higher temperatures f_s becomes a partition function for freely rotating water molecules. Since the strong hydrogen bonds will cause clustering in the gas phase, f_g includes a term for dimer water molecules. E_s and V_s are related by an equilibrium constant to the sublimation energies and solid volumes of the structured and unstructured species. Preliminary calculations indicate that the results for water will be nearly as good as has been obtained by significant structure theory for other pure liquids.

Conclusions

This theory can be applied to a tremendous range of liquids, and the degree of success has ranged from excellent to good. There is no other theory which will work as well for so many different classes of liquids. The theory rests on a model of the liquid state which is reasonable and successful. Its usefulness cannot be doubted. Given some properties of the solid (the sublimation energy, the volume of the solid, and the Einstein characteristic temperature) all the thermodynamic properties may be calculated from equations (12) and (13) and similar expressions. To determine n and a, the liquid volume, V_m, at the melting point must be known. Using an initial guess of V_m and a method of successive approximations, we can obtain consistent values for n and a. In those cases when the properties of the solid are unknown or for some special liquids, the parameters E_s, θ, and V_s may be determined from the experimental pressure, entropy, and liquid volume at the melting point.

The usefulness of the model is clear; the meaning of the model needs careful elaboration. Since the model can be applied to so many different liquids, can be used to calculate transport properties and surface tensions, and can be used to compute the radial distribution function, the basic tenents of the theory, while undoubtedly needing refinement, are none the less good approximations. Certainly the idea that a molecule in the liquid state sometimes possesses external vibrational degree of freedom and at other times translational degrees of freedom cannot be wrong. The division of these degrees of freedom into their respective fractions V_s/V and $(V - V_s)/V$ is a good first approximation and the estimation of the degeneracy factor needs elaboration.

A criticism frequently raised against this theory is that it has a number of adjustable parameters. We have tried to point out in this article that there are no adjustable parameters. The parameters E_s, θ, and V_s are obtained from the solid state. If there were a theory of solids, we could calculate these quantities; since there is not, we must obtain them by experimentation. The parameters a and n maybe obtained from equations (7) and (10). If all spherical molecules exactly obeyed a reduced equation of state, the same dimensionless values for n and a could be used for all liquids. In terms of a reduced equation of state an analogy can be drawn between T_c and a, and V_c and n. Since this theory is applicable to a greater degree of accuracy than a reduced equation, it is necessary to use accurate values of n and a.

A Chem Ed SYMPOSIUM

Kinetics for the Undergraduate

Introduction

This is an appropriate time to consider the place of kinetics in the undergraduate curriculum. In the not-too-distant-past, the subject was discussed primarily at two places. In the general chemistry course, kinetics appeared in inappropriate and generally incorrect derivations of the equilibrium constant expression. In the physical chemistry course, instruction in kinetics dealt largely with integration of rate laws of various forms. The relevance of kinetics in elucidation of reaction mechanisms was ignored, and even if not ignored, the instruction came too late to be of use in preceding undergraduate courses.

With presentation of more modern physical chemistry topics, e.g., molecular spectroscopy and quantum mechanics, instruction in kinetics is being crowded out of the standard undergraduate course in physical chemistry. The effect of this situation can be rectified and, in fact the situation improved with introduction of more meaningful discussion of kinetics in the freshman course. A reasonably sophisticated introduction to reaction kinetics and the meaning of rate laws in terms of reaction mechanisms is possible in general chemistry; this can be done within the framework of some of the existing textbooks or with the assistance of an appropriate elementary monograph.[1] Rate laws for chemical reactions then can be introduced where relevant in all later instruction in analytical, inorganic, and organic chemistry.

It is regrettable that textbooks on the reactions of chemical substances, both organic and inorganic, do not give more rate laws. Many textbooks give none. A model which authors of textbooks could imitate is Systematic Inorganic Chemistry by Yost and Russell,[2] in which there is, on the average, one rate law for every seven pages. Both the utility of kinetic data in elucidation of reaction mechanisms and their limitation can be illustrated very nicely with reference to specific examples in courses which focus attention on the chemical reactions. Theory and practice in chemical kinetics should be presented together.

The Division of Chemical Education sponsored a one-half day session on "Kinetics in the Undergraduate Curriculum" at the Los Angeles Meeting of the American Chemical Society in April, 1963. Six speakers discussed various facets of the subject, and it is fortunate that the following papers based on five of these contributions are being published in the JOURNAL OF CHEMICAL EDUCATION, which has also published other papers in the recent past on this same general topic.[3] In addition to the five papers being published here, a paper on "Reaction Rate Discussions Appropriate to the Elementary Organic Chemistry Course" was presented by J. D. Roberts of the California Institute of Technology. His paper discussed use of energetics of elementary reactions as an aid in deciding upon the correct mechanism for an organic reaction. The substance of this discussion can be found in his forthcoming book.[4]

It is hoped that those with interesting and novel ideas regarding instruction in kinetics will communicate these ideas to others by means of publication in THIS JOURNAL.

Concepts of Time in Chemistry

Chemistry is concerned with substances and with their transformations into other substances. One might expect therefore that the theoretical structure of chemistry would deal perhaps 50% with the nature of substances and 50% with the processes of transformation. The proportions are, however, very different, in part because a description of transformation processes at the molecular level has turned out to be peculiarly difficult.

About a century ago, Alexander Williamson in a paper on the implications of his synthesis of unsymmetrical ethers, commented (*1*):

> We are all agreed that chemistry is concerned with the material process of the transformations and changes which matter undergoes, and that the study of the properties of matter in themselves, as long as they undergo no change, belongs to physics. . . . When we study a molecule by itself, we study it physically; chemistry considers the *change* effected by its reaction upon another molecule, and has to describe the process by which that change is effected. A chemical decomposition should therefore be represented by the juxtaposition of the formulae of the reacting substances, and by effecting in these formulae the change which takes place in the mixture.

Williamson was well aware that no theory of chemical *transformation* existed in his time, and that a fundamental step away from the statical description of molecules was necessary in order to describe chemical change. His paper entitled "Suggestions for the Dynamics of Chemistry Derived from the Theory of Esterification" begins as follows (*2*):

> The human mind is only capable of understanding complicated phenomena when prepared by the study of simpler ones; and one of the most remarkable illustrations of this necessary order is afforded by the preparation of dynamical laws, by the consideration of statical facts. In statics we consider phenomena in a state of rest, while in dynamics we study their change; and this distinction has been concisely stated by saying that the transition from the statical to the dynamical point of view consists in superadding the consideration of *time* to that of space. . . . There are many *prima facie* evidences that *time* is necessary for chemical action—but this fact, although it has been noticed, has not yet entered into the explanation of phenomena.

Two comments should be made about this quotation. Firstly, Williamson identifies time as the necessary ingredient of any theory that is truly chemical. Secondly, his claim that time had up till then not entered into the explanation of chemical phenomena, if true, makes his theories the first truly chemical theories.

It is tempting to characterize the history of chemistry as a continual attempt to avoid the explicit incorporation of time into chemical theories. Williamson rejected the then current view that atoms and molecules are at rest. He called on chemists to study the "degree and kind of motion" possessed by atoms and to "reduce to this one fact the various phenomena of change, which are now attributed to occult forces (*2*)."

Williamson pointed to one piece of evidence of molecular motion in chemical reactions, the etherification of alcohol by sulfuric acid. It had been demonstrated that ethyl hydrogen sulfate is first formed, but that the latter gives up its ethyl group again to a second alcohol molecule:

$$C_2H_5OH + H_2SO_4 \rightarrow C_2H_5SO_4H$$

$$C_2H_5SO_4H + C_2H_5OH \rightarrow C_2H_5OC_2H_5 + H_2SO_4$$

Further, the two-stage process could be demonstrated by introducing a different alcohol, for instance amyl alcohol, for the second step. The repeated alternating process of a sulfuric acid molecule taking on an ethyl group from one alcohol molecule and supplying it to another almost necessitates molecular motion. Williamson also pointed to the fact of diffusion as clear evidence of molecular motion even in the absence of chemical reaction. He realized that the incorporation of motion into our concepts of chemical systems was the simplest way of incorporating the dimension of time into our atomic models.

A mechanism for a double displacement reaction was proposed by Auguste Laurent at about the same period. Laurent conceived of molecules in terms of geometric figures whose faces were occupied by atoms or groups. The benzoyl chloride-ammonia reaction

$$C_6H_5COCl + HNH_2 \rightarrow C_6H_5CONH_2 + HCl$$

he represented in terms of hexagonal figures, this being almost certainly the first time a hexagon was associated with a benzene derivative (*3*):

> To render the reciprocal replacement of the two residues intelligible, I will suppose, that in ammonia and chloride of benzoyl the atoms are arranged so as to form hexagonal figures.

Bz and A, Fig. 1, represent chloride of benzoyl and ammonia at the moment when they react upon one another, the face *c* being opposed to the face *h*, which is to be set free. Bz and A, Fig. 2, represent the two residues during the reaction, and Bz, A, Fig. 3, the two residues after the reaction having reciprocally filled up the two voids formed in A and Bz [by the removal of the chlorine and hydrogen "faces"].

Presented as part of the Symposium on Kinetics in the Undergraduate Curriculum before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

August Kekulé in his classic 1858 paper on the chain-forming capacity of carbon atoms, referred to Laurent's mechanistic proposal and devoted a section of the paper to a discussion of the "process that occurs during chemical metamorphoses" feeling that "the main cause of the lack of clarity in certain points of view is the one-sided conception held about such chemical changes (*4*)."

Kekulé's proposal, which he believed to be applicable to all reactions, was as follows (*5*):

> When two molecules react, they first attract each other by virtue of their chemical affinity and align themselves next to each other. The affinities of the individual atoms then cause atoms which previously belonged to different molecules to come into intimate contact. For that reason the group that was divided in one direction prior to reaction, now falls apart in another direction, thus:
>
> | Before | During | After |
> |---|---|---|
> | a \| b | a b | a b |
> | a′ \| b′ | a′ b′ | a′ b′ |
>
> . . . In the majority of cases, the force that occasioned the molecules to come together also causes the resulting decomposition; on the other hand it is conceivable, and cases of this sort exist, that the affinities of the atoms belonging to the different molecules will lead to the association of the molecules, but, at least under the same conditions, will not lead to the decomposition of the atomic aggregate so formed into two new molecules.
>
> Of especial interest, therefore are the cases in which the intermediate state [*Zwischenstadium*], the molecular aggregate, can be retained, but where by deliberate changes in the conditions, the decomposition can be brought to completion.

Kekulé has here proposed, probably for the first time, the mechanism we still accept for the hydrogen-iodine reaction. Both he and Laurent proposed an intermediate stage between initial and final states and Kekulé pointed to the importance of isolating such intermediate stages or molecular aggregates. He referred to a reaction of cacodyl chloride, $As(CH_3)_2Cl$, with chlorine where an addition product could be isolated which on mild heating decomposed into methyl chloride and arsenic monomethyl dichloride. He assumed that NH_4Cl and PCl_5 were analogous to these intermediate addition compounds except that they decomposed only in one direction, the direction from which they were formed.

In a footnote Kekulé explained the phenomena of mass action and catalysis as due to a pervasive loosening of the bonds between atoms due to affinities between unbonded molecules. If two substances are both reagents, larger concentrations lead to a greater weakening of bonds, hence to faster reaction. If one of the bond-weakening substances is not a reagent, it acts as a catalyst (*5, 6*).[1]

The historical background here given is very different from the one usually mentioned when introducing chemical kinetics, namely, Wilhelmy's study of the inversion of sucrose in 1850, Guldberg and Waage's studies on mass action in the 1860–70's and Arrhenius' work on activation energy in 1899. The *idea* of a transition state or intermediate state predates by many decades the mathematical procedure for obtaining its energy. Kinetics does not deal only with the quantitative elucidation of rates or reaction. Its main value to chemists is in the aid kinetics gives in the elucidation of mechanisms. Therefore *both* historical strands, the concern with mechanism—that is, with the nature of the process of chemical change—and the concern with the variation of reaction rates with changing conditions, were necessary for the modern emphasis on kinetics. Unfortunately however, kinetics still is often taught tucked away in a corner of a physical chemistry course, seemingly completely unrelated to the mechanisms discussed in organic and inorganic chemistry courses. The concern for an understanding of the *process* of transformation, and for the incorporation of the time dimension in chemical discussions is seen to have a venerable history. In what ways has time been incorporated into chemical concepts?

[1] A very rudimentary idea of a transition state was already envisaged by William Higgins in 1789 in discussing the reaction of iron with hydrochloric acid. *Cf.* ref. (*6*).

Concepts of Time

Diffusion. As Williamson pointed out, time is involved in the phenomenon of diffusion and is incorporated in the simple application of a Newtonian model to chemical substances. The movement of material is explained in terms of velocities possessed by individual molecules. But any property possessed by a molecule as a whole cannot by itself account for transformations occurring within the molecule.

The First Law of Thermodynamics. The first law of thermodynamics deals with the convertibility of different forms of energy and enunciates the principle of energy conservation. Time enters only implicitly, convertibility implying at least two states of a system at different times. But as far as the first law is concerned, energy conversion can occur in any direction. Time only appears as a way of separating before and after. There is no necessary connection between a set of events and time. As a mathematical model all that is needed is the pair of numbers 0 and 1, the 0 representing the earlier and the 1 the later state. The numbers may be interchanged without breaking the first law. If heat is gained in a reaction going in one direction, exactly the same amount of heat will be lost for the same number of moles of material reacting in the opposite direction.

The Second Law of Thermodynamics. The second law, in contrast with the first, demands an intrinsic connection between time and the world of events. It is the chemist's way of recognizing the interconnection of space and time demanded by relativity theory. A chemical system under certain conditions undergoes certain chemical changes and not others. The events occur in a particular sequence in time. Time's "arrow" is introduced imposing a serial order on certain sets of states. In a sense all chemical changes are spontaneous changes. Under specified conditions, change occurs only in a given direction, the direction of free energy decrease. To force a reaction in the reverse direction is simply to change the state of the system until the reverse chemical change involves a free energy decrease. A mathematical model for the time concept in the second law of thermodynamics might be the continuum of increasing real positive numbers. Any number must be followed by a larger one, as any state must be followed by one of lower energy. Only the uni-directional character of time is required here, not any quantitative measure of time. There are no specific numbers indicated on the number continuum.

Perhaps a better model for time as here discussed is as a lengthening ribbon whose only specification is that it always grows longer without any specification as to its rate of growth.

Kinetics. The second law of thermodynamics could predict a future state from a present one but was quite incapable of predicting the time required to attain the future state. No measure of time, no time unit was specified in the equations of thermodynamics. There seemed to exist an unbridgeable gulf between thermodynamics and the study of chemical kinetics. For kinetics uses a time concept incorporating a unit of time, against which the quantity of chemical change per unit time can be measured. That unit of time is in the last resort dependent on certain periodic phenomena, the rotation of the earth, the pulse beat, the swing of the pendulum, the oscillation of a balance wheel, a vibration in a molecule, one of which is taken to be a truly periodic motion in terms of which other time spans are determined. It is perhaps of more than incidental significance that the transition from the second law of thermodynamics to kinetic studies of rates of chemical change has its exact counterpart in the history of geology. Until the turn of the century geologic events could only be ordered on a serial time scale, with almost no indication of the quantitative time spans between events. Radioactive dating techniques have now supplied a *measure* of time so that a definite date can be assigned to a geologic event.

Two paths have been followed theoretically in relating kinetic data and energy conceptions. The first, the collision theory, employing a Newtonian model, incorporates time by using molecular velocities and attempts to determine the number of favorably oriented collisions which also have the requisite amount of energy.

The second, known as the theory of absolute reaction rates, bridges the gulf between thermodynamics and kinetics, that is between energy and time units by means of the Planck expression $E = h\nu$. Here an equivalence, a conversion factor between energy and frequency is postulated, making it dimensionally possible to deduce rate data from energy data. The particular frequency that introduces the time dimension into thermodynamic relations is the computed frequency of the loose bond in the transition complex which is broken during the decomposition of the complex. (*7*).

The application of thermodynamics in the theory of absolute reaction rates implies that the transition state can be treated as any other thermodynamic state, that its properties are independent of the path by which it was attained, that there exists an equilibrium between the initial state and the transition state and one between the transition state and final state. Much has been written about this assumption and it has been repeatedly questioned (*8*).

Clearly, if the transition state were in equilibrium with the initial state no chemical change would occur. As Eyring and Eyring have recently pointed out (*9*), The Introduction to the recent British symposium on the transition state validly points out that the greatest success of transition state theory "has been not in the accurate prediction of the rates even of the simplest reactions, but in providing a framework in terms of which even the most complex reactions can be better understood (*10*)."

Particularly organic chemists have attempted to describe reaction paths in terms of transition states and intermediates, endowed with all the properties of stable thermodynamic states. We are in danger at times of forgetting that by so doing we are once more removing the time dimension and are attempting to explain a continuous temporal process in terms of a set of purely static spatial images. In a reaction

$$A + B \rightarrow C^* \rightarrow \text{products}$$

where C^* is an assumed intermediate, if a different reaction

$$P + Q \rightarrow C^{\ddagger} \rightarrow \text{products}'$$

gives even a slightly different proportion of products, it is sometimes assumed that the two intermediates C^* and $C^{\ddagger}$ cannot be identical. It is assumed that the same intermediate under the same conditions must always lead to exactly the same products. This of course must be true if C^* and $C^{\ddagger}$ are proper thermodynamic entities; but that is precisely the question at issue. What sort of minimum stability must an entity have, how deep must the energy trough be to allow us to be certain that its decomposition is not influenced by the path by which its conformation was attained?

As an example, we may cite the discussion of a number of years ago regarding the existence of two species I and II

I II

produced from different sources and leading to different products and showing markedly different rates of deuterium exchange. The π-complex I was postulated as an intermediate during the hydration of olefins, while the hydrogen bridged intermediate II was suggested as perhaps only a transition state during the deamination of isobutylamine. Now according to resonance theory, the nuclei in I and II are in such similar locations that I and II should simply be resonance structures approximating the actual distribution of nuclei and electrons. Yet it was felt that since the two postulated intermediates led to different products, they cannot have the same structure and were considered as structural isomers (*11*). An alternative proposal is, of course, that I and II may very well represent the same momentary set of locations of nuclei and electrons but that the energy trough of the intermediate is so shallow that the future course is markedly dependent on the past history, on the *direction* of motion of the particles constituting the intermediate (*12*). To represent such a difference in history by the two structures I and II is to translate

A metastable state such as the activated complex arising from reactants almost always goes on to products and does not equilibrate in the way characteristic of stable states. Instead, at equilibrium, products pass in the reverse direction through the metastable, activated states to maintain the balance characteristic of equilibrium.

temporal differences into differences in spatial arrangement. It is one more attempt to avoid the dimension of time.

The above considerations suggest that perhaps organic chemists have reached the point where the profusion of postulated intermediates and transition states may necessitate in the not too distant future a shift from the purely spatial imagery now current to a truly dynamic model, one that attempts to depict the continuous processes of chemical change.

Kinetics in the Earlham Curriculum

What is being done at Earlham in the way of teaching kinetics can be stated rather briefly. We have felt that to relegate kinetics to a late portion of a junior or senior physical chemistry course is both temporally and spatially wrong. If the physical chemistry course is the capstone course, kinetics is taught too late. It is taught *after* most of the chemistry to which it is applicable has been described and therefore described inadequately. And precisely the same reason demands that kinetics not be taught as one of a number of selected topics of theoretical chemistry, but that it should be taught instead within the context of organic and inorganic subject matter that gives kinetics its relevance to chemistry.

On the other hand, we did not feel that the subject could be adequately treated merely by occasional mention in other courses. Somewhere the kinetic approach had to be presented systematically. Our solution, which was in keeping with our general approach at Earlham of tying each course as far as possible around one or two central concepts, was to design a junior level course focussing on the concepts of space and time in chemistry, that is, dealing with the topics of stereochemistry, kinetics and mechanisms (*13*). Each of these topics had been introduced many times in earlier courses; in this course earlier fragmented information was synthesized and systematically extended. Stereochemistry was discussed in terms of both inorganic and organic compounds and included a more than cursory look at conformational analysis. Kinetics included discussion of the conceptual bases and uses of the theory of absolute reaction rates. The mechanisms of a number of reactions were discussed in detail with regard to their stereochemical and kinetic properties. At the end of the course each student reported on the kinetics of a reaction recently published in the chemical literature.

In the laboratory we spend about one-third to one-half of the term on kinetic experiments and the balance on qualitative organic analysis. With only majors in the course, the course is taken by six to twelve students. The kinetics work is done mainly on a project basis, the students working in pairs. In addition to one or two classic introductory kinetic experiments, the students work on one or sometimes two detailed kinetic projects. These have included:

- Rate of mutarotation of α- and β-glucose.
- Rate of inversion of sucrose.
- Colorimetric determination of diazocoupling rate.
- Conductivity determination of alkyl halide solvolysis.
- Use of concentration cell for following rapid reactions (*tert*-butyl chloride solvolysis).
- Spectrophotometric study of kinetics of chromic acid oxidation of 2-propanol.
- Basic hydrolysis of benzyl chloride.
- Halogen exchange reaction of alkyl bromides.

Having taken this course in his junior year, the student should be well prepared for independent study projects as a senior or for research participation with a faculty member during the summer preceding his senior year.

Kinetics—Early and Often

Most chemists agree that the measuring and understanding of the rates of chemical reactions and the mechanism by which they occur are important activities in chemistry. It is therefore somewhat surprising that any reasonable discussion of these areas is normally deferred until the third or fourth year of college. Rates may be mentioned in first year chemistry courses, such as are given in high schools, and the effect of concentration and temperature generalized. But the impression is almost always given that a study of the equation for the net reaction provides evidence for the factors which will affect the rate and that the equation will enable one to predict from it which concentrations will have what effect on the rate.

Chemistry, at these early stages, almost always concerns itself with the nature of the products and the reactants and with the equilibrium between them. But it very seldom deals with that interesting phase of chemistry (represented by the equal sign) through which the reactants do indeed become the products. Rate experiments, when performed, usually corroborate the erroneous idea that the net reaction is intimately related to the rate equation, either by presenting only qualitative evidence as to the effect of concentration, or by dealing with systems in which the mechanism is so simple that there is a pseudo-correspondence between the net reaction and the rate equation. Even when rates and mechanism finally are approached at a higher level, they are seldom dealt with on an experimental basis so that few of the interesting features of mechanisms are met in the laboratory.

There has been considerable justification for this approach in the past when the mechanisms of very few reactions have been completely understood, when rate data have been hard to obtain, and when the majority of chemists have actually been more interested in other areas. None of these "rate determining factors" seems, however, to be effective now.

The studies of rates and mechanisms in chemical reactions has now become central to the understanding of chemistry. Thus, it seems most important to introduce a reasonable discussion of these ideas in the earliest course in chemistry and to reinforce these ideas in each subsequent course, basing the approach as firmly as possible on experimental observations directly accessible to the student.

Let me first list the areas which seem to be important for a minimally educated college graduate (not necessarily a chemist) to have understood in connection with rates and mechanisms and then outline possible sequences by which the total picture might be achieved in the mind of the student. I would choose to classify these ideas into three main categories:

The variables which ordinarily affect the rate of chemical reaction.

The mechanism by which the chemical reaction actually occurs.

The relationship of this mechanism to the equilibrium.

In order to approach most directly the relationship of the variables affecting rate, it seems feasible first to study the rate and to determine experimentally the rate equation. In such an equation the rate of change of some concentration is expressed as a function of certain concentrations and, at any given temperature, a constant. For example,

$$d[\mathrm{HBr}]/dt = k\,[\mathrm{H_2}]\,[\mathrm{Br_2}]^{1/2}$$

for the initial stage of the net reaction

$$\mathrm{H_2} + \mathrm{Br_2} \rightarrow 2\mathrm{HBr}$$

In some cases this differential rate equation can be integrated to give an expression for the concentration of each variable as a function of time and the additional concentrations. For example,

$$\log(\text{ester}) = kt + C$$

for the net reaction

$$\mathrm{H_2O} + \mathrm{CH_3COOC_2H_5} \rightarrow \mathrm{CH_3COOH} + \mathrm{C_2H_5OH}$$

It is interesting to observe that there is no general relation between either the differential or integrated form of the rate equation and the equation for the net reaction. In many cases the rate of reaction is unaffected by changes in concentrations of some of the reactions. For

$$2\mathrm{NH_3}(g) \rightarrow \mathrm{N_2}(g) + 3\mathrm{H_2}(g)$$

on a tungsten surface the rate is independent of the concentration of ammonia. In many other cases the concentrations of substances appear in the rate equation whereas these substances do not appear in the equation for the net reaction. The rate of the net reaction

$$\mathrm{C_{12}H_{22}O_{11}} + \mathrm{H_2O} \rightarrow 2\,\mathrm{C_6H_{12}O_6}$$

in dilute acid is given by

$$d[\mathrm{C_{12}H_{22}O_{11}}]/dt = k[\mathrm{C_{12}H_{22}O_{11}}]\,[\mathrm{H^+}]$$

Furthermore, there is no general correlation between the exponent of each concentration, or the form in which it appears in the rate equation, and the coefficient of the corresponding substance in the equation for the net reaction. Thus, the general rate equation is

Presented as part of the Symposium on Kinetics in the Undergraduate Curriculum before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

$$\frac{d[\mathrm{HBr}]}{dt} = \frac{k_1[\mathrm{H_2}][\mathrm{Br_2}]^{1/2}}{k_2 + [\mathrm{HBr}]/[\mathrm{Br_2}]}$$

for the net reaction

$$\mathrm{H_2} + \mathrm{Br_2} \rightarrow 2\mathrm{HBr}$$

This comparison of experimental net equations and experimental rate equations quickly leads to the conclusion that any correlation between the two must be quite coincidental or, at least, very well hidden by the intricacies of any relationship.

The effect of temperature on the constant in the rate equation is often experimentally calculable since, in general

$$\frac{d \log k}{d[1/T]} = \frac{\Delta H_{\text{activation}}}{\mathrm{R}}$$

A plot of the logarithm of the rate constant versus the reciprocal of the absolute temperature commonly approximates a straight line from whose slope k may be calculated.

No variables other than certain concentrations and the absolute temperature are ordinarily found to affect the rate of a given chemical reaction.

It is quite true that there are reactions, particularly those occurring on solid surfaces, where it is extremely difficult to express the concentration. But it is commonly accepted in these cases that the difficulty is in defining the concentration rather than being based on a new kind of variable.

It is, of course, quite possible to interpret these concentration and temperature variables in terms of various theories, but I will leave the discussion of such theories to the authors of other papers and adhere here to a discussion of some experimental observations with minimum reference to collision or activated complex theory as such.

Mechanism of Chemical Reactions

A major principle for the understanding of the mechanism of chemical reactions is committment to the idea that all mechanisms are possible, but that some mechanisms proceed more rapidly than others, and that normally the observed rates are determined by a single mechanism—that which is most rapid. Many systems are known in which simultaneous or parallel reactions occur, but many others can be adequately treated in terms of a single predominating mechanism.

In a typical predominating mechanism many steps may occur. These always, of course, involve the collision of certain reacting molecules and the formation of intermediate molecules. The intermediate molecules then continue to react in further steps of the reaction to produce the final products. Some reactions involve very complicated mechanisms and others relatively simple mechanisms, but in many cases the overall rate of the reaction is primarily determined by the rate of a single step known as the slow step of the reaction mechanism. When there is a single slow step the experimentally determined rate equation and the experimental dependence of the rate constant on absolute temperature turn out to be especially simple.

Finally, in the mechanisms of many chemical reactions the intermediate products are highly reactive and can exist only at small concentrations. In many cases, these concentrations build up as the reaction begins to a level which remains quite constant during the major course of the reaction. Such concentrations are said to experience a *steady state*. Substances having a steady state concentration are being formed and reacting at the same rate so that their net concentration at any time is constant.

Thus, one writes down various plausible mechanisms and compares the rate equation calculated from the assumed mechanism with the experimental one. Often only one mechanism is found which gives concurrence with rate and other (e.g., energetic) data. Such a mechanism is, then, assumed to be correct.

Equilibrium and Kinetics

Once the general mechanism of a reaction is understood, it is easy to demonstrate, by applying the principal of micro reversibility, that the equilibrium state involves a set of simultaneous reactions in which every step in the mechanism is proceeding in both directions at equal rates. It is also easy under these conditions to show the relationship of the rate expressions to the equation for the net reaction. The sum of all of the mechanistic steps must give the equation for the net reaction. Ordinarily the equation for the rate of reaction, if there is a single slow step, depends only on the concentration of the reactants in that slow step and on the absolute temperature of the system.

Applicability of Mechanistic Ideas in Early Chemistry

It is difficult to see why the ideas presented above which summarize most of the major points important in understanding rates and mechanisms of reaction cannot be presented at a much earlier stage than is now done. It further seems possible that presenting such ideas at an early stage would allow students to have a new comprehension of what actually occurs in chemical reactions and, thus, a much better understanding of the nature of chemicals and their interactions with one another. The problem remains to devise experimental methods of illustrating these ideas. It seems especially important to devise experiments which the students can themselves perform and from which these ideas become dramatically underlined. May I therefore suggest at least one experiment which seems to fulfill some of these criteria.

The "Blue Bottle" Experiment

Let us consider a chemical system which is very easily constructed and on which very simple experi-

The Cover

The "blue bottle" experiment fascinates everyone who tries it. Best of all, it teaches much. Here Karen Benker, a pre-med sophmore from Pomona College, and James Edwards, a junior chemistry major from Harvey Mudd College, intepret their summer research activities under NSF sponsored URP program at Harvey Mudd to inspect the unexpected.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

ments can be done by students with a minimal experience in chemistry.[1] I have used this experiment with students from the 7th grade through graduate school with considerable success at all levels. Even faculty members seem to be pleased with the observations and conclusions which can be made in connection with it. The system normally consists of a glass flask approximately half full of a clear colorless liquid with a rubber stopper in the top. Shaking the flask causes the liquid to turn blue. Upon standing the blue liquid reverts to its original colorless condition. Shaking initiates a further bluing, then de-bluing cycle. Students of all degrees of sophistication seem to enjoy suggesting interpretations of these observations. It is commonly suggested that there is a colored material on the stopper or that the increased contact with the glass on shaking causes the color change. These ideas are readily checked experimentally by up-ending the flask or by gently swirling it so that the liquid does cover the glass or touches the stopper. In neither case does the blue coloration appear.

Perhaps the most obvious change in the flask upon shaking is that the kinetic energy of the contents is increased. This leads to the idea that the rise in temperature causes the blue color with the subsequent loss in heat as the flask cools back to room temperature allowing the color to revert. Again this can be readily checked experimentally by warming the flask in one's hands and showing that the blue coloration does not occur.

The common suggestion at this point is that there are two layers which are mixed when the flask is shaken and then separate. This can be quickly checked by again up-ending the flask and noticing that the blue color disappears uniformly in the long cylindrical neck rather than rising or falling as would be true were there two layers which were separating. A similar suggestion is that shaking may mix any gas which is in the top of the flask with the liquid and that upon standing the gas separates from the solution again. This can also be experimentally checked just as the earlier two layer theory, since it is only a special case of it. Again the uniform disappearance of blue color throughout the flask indicates that this suggestion is not acceptable. Note that each suggestion fits all the observations made up to that point, but can be shown to be inadequate to fit further possible observations.

Once the idea that there may be a gas in the top of the flask arises, it becomes apparent that this may indeed be a reactant which does not later escape from the solution. Students quickly suggest various ways of checking this theory. Assuming that the gas pressure was originally atmospheric this pressure should have dropped and gentle removal of the stopper should show bubbles in the inside of the "liquid seal" around the stopper. It is wise to point out at this time that this may seriously affect the experiment by contaminating the contents of the flask with air. However, the experimental check does indeed show that the pressure is less than atmospheric and further shaking will again reduce the pressure below atmospheric. An even more clever way of checking the possibility that a gas is entering the liquid and causing the blue color is to observe the interface between gas and liquid. If the theory is correct there should be a thin blue layer where the mixing is continually occurring. Close examination shows this layer. The fact that the layer is not

[1] I found this experiment at the University of Wisconsin in 1954, but heard it was discovered at Cal Tech.

Clitheroe Royal Grammar School for Boys
York Street
Clitheroe, Lancashire
July 10, 1963

Dear Professor Campbell,

Following your lecture on "Chemical Study" at University College, London a week ago, and the few minutes conversation we had at the Middlesex Hospital Medical School, I yesterday gave a small group (seven) of my boys a flask with the methylene blue (caustic soda) glucose solution and asked them to deduce as much as they could about the chemistry of the system from what they could observe, without the use of any other reagents. They are all aged 18 and have just attempted "A" level chemistry. They were given no help or suggestions by me. One boy acted as "scribe" for the group and I enclose his rough notes (in red) and his report (in blue). The first side of the (blue) was done at the time of observation; the remainder was done after 24 hours thought by the boys. The train of reasoning is fairly clear (and it is interesting to note that at one time they thought the liquid had three reactive components X, Y, and Z).

Norman Thorpe
Senior Chemistry Master

thick coincides with the observation that the blue color disappears on standing. So, in the case of the surface layer, the blue color disappears as it diffuses into the bulk liquid. A further quick check can be run by replacing whatever gas is in the flask, normally air, by natural gas. Shaking the liquid with natural gas does not cause any blue coloration. Replacing the natural gas with air and repeating the shaking again causes the blue coloration which disappears on standing. One now has fairly conclusive evidence that some ingredient of air does indeed react with the liquid to form the blue solution.

By this time one will almost certainly have observed that the rate of the initial "bluing reaction," while not instantaneous, is quite rapid, occurring in a few seconds, whereas the disappearance of the blue color takes much longer depending on the conditions but approximating twenty seconds or so. This allows the tentative conclusion that there must be at least three reactions occurring in the flask. There is the solution of the gas in the liquid phase, followed by a reaction with something in the liquid to form the blue color, followed in turn by the reaction of the blue material to produce colorless products. We can tentatively represent this reaction mechanism (note that the student has arrived at this mechanism without any knowledge of the chemical ingredients of the flask and on the basis of very simple observations which can be made in any classroom) by the following scheme:

$$A(g) \rightarrow A(soln)$$
$$A(soln) + X \rightarrow B$$
$$B + Y \rightarrow \text{products}$$

Suggested mechanism 1

In this scheme A represents the original gas; B represents the blue material; X represents the reactant which converts the gas to the blue material, B; and Y represents the substance which reacts with B, the blue material, to give colorless products. It is interesting to note that essentially every group with whom I have discussed this experiment has arrived at this mechanism without very much prompting. The question now reads: Is the mechanism adequate to interpret all the experimental evidence? The answer is that it does indeed interpret all the experimental evidence observed so far by most of the people, but not all of the experimental observations which actually can be made. For example, perspicacious students will already have noticed that the length of time the solution remains blue depends on how long one shakes the flask. Very few will have specifically noted that it is also true that the intensity of the blue color is independent of how long the flask is shaken. These two bits of information, however, are readily observed and prove to be very important in continuing a study of the mechanism.

It is relatively easy to show, with an approximation to quantitative measurements, that the length of time the solution stays blue is directly proportional to the degree of shaking. One shake may cause blue color for ten seconds, two shakes for about twenty seconds, four shakes for about forty seconds and so on. Thus, the time the flask stays blue depends directly on the time of shaking. This is certainly consistent with the first step in the reaction scheme above in that one would expect more gas to dissolve if one shook longer. It is not readily consistent, however, with the second step. One might guess, if one increased the concentration of dissolved gas that the second step of the reaction would

---

(Blue) notes from students

Examination of the contents of a flask

Shakes given to flask	Time to return to original color (sec)
1	10
2	15
3	20
4	25
5	30

On shaking, the solution turned blue, the intensity of the colour depending on the time shaken. The blue colour then faded back to the original colour.

The experiment was repeated in the dark. The times were the same showing that the solution is not light sensitive.

The apparent suspension in the liquid always remained white.

On removing the bung, air was heard to enter the flask. This suggests that some of the gas is permanently absorbed. This is confirmed by a permanent blue colouration which remains round the meniscus of the liquid. On tilting the flask a permanent ring appeared on the glass of the flask, corresponding to the meniscus of the liquid. On placing a glass stirring rod in the solution the blue ring formed around it. This suggests possibly that the glass is catalyzing the reaction.

The reasoning was then continued 24 hours later.

The first thought was that a reversible reaction was taking place. Since however the pressure is reduced inside the flask this theory is not altogether true. This reduction in pressure might be attributed to the gas absorbed on the surface (the blue colour shows this) but if the surface absorbs the gas, why does not the whole solution absorb gas. This leads us to think that the first reaction is one in which the gas is absorbed by the liquid. The equation for this step might be.

gas + first component of solution → blue compound

This is a fairly slow reaction. The blue compound then reacts with another component of the solution.

blue compound + second component of solution → new compound (colourless) + first component of solution

This is a very slow reaction.

The overall equation is

Gas + second component of solution → new compound

It would thus appear that one component of the solution is acting as a catalyst.

The slight blue colouration on the surface of the liquid is explained as follows: The gas reacts with the surface of the liquid to form the blue compound. The blue compound then reacts with the second component to form the new compound. Hence the second component near the surface of the liquid is all reacted and hence the blue colouration is permanent.

Conclusion

It would appear that the reaction taking place is of the general form

$$\underset{\text{catalyst}}{A + B} \rightarrow \underset{\text{addition compound}}{AB}$$

$$AB + C \rightarrow AC + \underset{\text{catalyst}}{B}$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

proceed more rapidly and that increasing the initial concentration of dissolved gas by a factor of four would not cause the reaction to take four times as long. The time would certainly increase as there is more gas to remove, but it should not increase four times. Furthermore, the fact that the blue color lasts longer as the concentration of dissolved gas is increased is not directly consistent with the fact that, even though the concentration of dissolved gas may have increased, the intensity of the blue color, which apparently measures the concentration of an intermediate substance, does not increase. As a matter of fact, the constant level of the blue color would indicate that the concentration of this intermediate rather quickly reaches a steady state which is maintained throughout the body of the reaction, rather quickly dropping from a steady state value to zero as the de-bluing reaction nears completion.

How do we account for the lengthening of the time the system stays blue, while simultaneously accounting for the constant intensity of the blue color regardless of the concentration of dissolved gas?

At this point, students typically suggest many possible alternatives which can be explored experimentally. The weight and amount of experimental evidence is now so great that it is relatively easy to discard most of the theories which are presented. One theory which is not so readily discarded, however, is that X is actually a limiting reagent in the second step of the mechanism above. Perhaps increasing the concentration of dissolved gas cannot give any more blue color than can be formed from the limiting amount of ingredient X. It rather quickly follows from this hypothesis that if the blue color is to remain constant and yet be reacting in step three, X must be regenerated in step three and be a product. This is consistent with the observed fast rate of the second reaction and slow rate of the third. Thus, we might modify reaction three above to read:

$$B + Y \xrightarrow{\text{slow}} X$$

We now have a scheme which fits all the observations made so far. The constant level of blue color is reached because X is a limiting reagent which reacts rapidly with the dissolved gas forming the blue intermediate. The blue intermediate slowly reacts with Y regenerating X which quickly forms more blue intermediate by reacting with further dissolved gas. As the dissolved gas is completely used up, X remains in its colorless state and no more blue intermediate can be formed.

We now have a scheme which is consistent with all the observations which can be readily made merely by shaking the flask. However, we have not exhausted the possibilities which the system offers for exploration. For example, adding the three steps does not give a net reaction!

$$A(g) \xrightarrow{\text{fast}} A\,(soln)$$

$$A(soln) + X \xrightarrow{\text{fast}} B \qquad \text{Suggested mechanism 2}$$

$$B + Y \xrightarrow{\text{slow}} X$$

$$\text{Net: } A(g) + Y \longrightarrow ?$$

No product is indicated. This can be corrected by using scheme 3.

$$A(g) \xrightarrow{\text{fast}} A(soln)$$

$$A(soln) + X \xrightarrow{\text{fast}} B \qquad \text{Suggested mechanism 3}$$

$$B + Y \xrightarrow{\text{slow}} X + \text{products}$$

$$\text{Net: } A(g) + Y \rightarrow \text{products}$$

It is now possible to explore the effect of concentration on the rates of reaction. Since one does not know the chemical contents this can be done most readily by adding water to the flask. To the surprise of most students, the addition of water turns the contents of the flask blue. This surprise is rather quickly resolved when one remembers that there is dissolved air in water, and that it is this dissolved air which is almost certainly causing the blue. (As a matter of fact, this experiment turns out to be a rather good method for analyzing for dissolved air (oxygen) in waters and can be calibrated to give rather accurate and reproducible results.) Once the blue color caused by the added water has disappeared, one does indeed find that the rate of the de-bluing reaction has decreased, in fact it has decreased rather markedly. Another effect of decreasing the concentration of X is that the intensity of the blue color decreases, consistent with our mechanism. Thus, the concentration of X, and hence B, will have decreased by adding the water as well as the concentration of Y. The effect of decreasing the concentrations of B and Y, since they react in the slow step in the mechanism is that the overall mechanism slows down as observed. One might predict therefore that doubling the volume by adding an equal volume of water would decrease the rate of the slow reaction by a factor of four, since both B and Y decrease by a factor of 2 in concentration. Actually the rate drops more than this indicating that there is a complication of the mechanism not yet anticipated.

By this time, students will probably have noted that the solution is slippery. This indicates that it is probably basic. Since it is basic it may well be that the presence of base has some effect on the reaction mechanism. This is actually the final clue which is needed completely to unravel the mechanism because it is true that although hydroxide ion does not react in the rate determining step nor in the net reaction (as is true of B also), it is important in determining the overall rate of reaction. We thus find that the experimental rate equation for this reaction is

$$\frac{d[B]}{dt} = k[B]\,[Y]\,[OH^-]$$

Note that it is impossible, as is generally true, to guess the rate equation from the equation for the net reaction

$$A + Y \rightarrow \text{products}$$

Also note that the only chemical we have identified so far is hydroxide ion.

However, even without identifying the chemicals it is possible to study the effect of temperature on the rate of reaction by plotting the logarithm of the de-bluing time for a constant amount of dissolved gas as a

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

function of the reciprocal of the absolute temperature, $1/T$. This is possible, because the rate of the slow step is independent of the concentration of oxygen and thus the time, t, it takes the total oxygen to disappear is directly related to the rate constant k. A straight line is obtained from a log t versus $(1/T)$ plot. (From this one can of course obtain the activation energy for the slow step.)

The actual system can be made up in a very rough fashion, but should contain approximately 20 g of sodium hydroxide, 20 g of glucose (reactant Y), and perhaps half a milliliter of 1% alcoholic methylene blue (reactant X) solution per liter of water. There is nothing very critical about these reactants and they need not be weighed out. It then becomes apparent that the system involves the oxidation of glucose by oxygen (reactant A) catalyzed by methylene blue.

Even without identifying the chemicals, it is possible for students to see that ingredient X is a catalyst for the reaction, since it is consumed and then regenerated in the reaction. Thus X appears in the rate equation but does not appear in the equation for the net reaction. This system is one of the few in which the intermediate molecule formed by the catalyst is actually visible. Thus, the system provides valuable support to any discussion of the nature of catalytic action.

The role of hydroxide ion is somewht more difficult to see and cannot be deciphered completely without a knowledge of the ingredients involved. The actual role of the hydroxide ion is to convert glucose, G (formerly called reactant Y), to the glucoside ion, G^-, in a rapidly reversible equilibrium. It is apparently the glucoside ion which is involved in the actual rate determining step.

$$\begin{array}{lll}
1. & G + OH^- \overset{\text{fast}}{\rightleftharpoons} G^- + H_2O & \\
2. & A(g) \xrightarrow{\text{fast}} A(soln) & \\
3. & A(soln) + X \xrightarrow{\text{fast}} B & \text{Suggested mechanism 4} \\
4. & B + G^- \xrightarrow{\text{slow}} X + \text{products} & \\
\hline
 & \text{Net: } G + A(g) \longrightarrow \text{products} &
\end{array}$$

The introduction of the equilibrium constant for the rapid reversible equilibrium allows one to show, however, that the rate can be expressed in terms of glucose concentration and hydroxide concentration, as we found experimentally to be the case.

Thus, for the slow step (and hence the whole mechanism)

$$\frac{d[B]}{dt} = k_4[B]\,[G^-]$$

where B is the oxidized (blue) form of methylene blue. But

$$K_{eq_1} = \frac{[G^-]}{[G]\,[OH^-]}$$

$$[G^-] = K_{eq_1}[G]\,[OH^-]$$

$$\frac{d[B]}{dt} = k_4 K_{eq_1}[G]\,[OH^-]\,[B] =$$

$$k[G]\,[OH^-]\,[B] = k\,[\text{glucose}]\,[OH^-]\,[\text{methylene blue}]$$

which agrees completely with the experimentally determined rate equation. Note the reaction is zero order in oxygen, the gas A, from the air.

It is now interesting to note that we have indeed introduced, with a very simple system, and very simple observations, most of the important ideas concerning the mechanism and rates of chemical reactions which it is normally considered a student entering graduate school should have. And we have done this at the level of a first course in chemistry. One can also point out that the reaction is susceptible to quantitative measurements in a laboratory. In terms of these quantitative measurements and an actual knowledge of the ingredients, it is quite possible for the student to gain great insight into the effect of changing concentrations or temperature on a reaction mechanism.

It is further profitable to point out to the student the analogy between the role of methylene blue in the oxidation of glucose in this system and that of hemoglobin in physiological systems where glucose is oxidized. Students prove to be quite interested also in the tie-in with the use of methylene blue as an antidote for carbon monoxide poisoning in the blood, and the mechanism of its action.

Kinetics—Early and Often

It is for reasons such as those presented above that the Chemical Education Material Study has made a serious effort to introduce the major ideas concerning rates of reaction and reaction mechanism in a clear and correct fashion in a first course in chemistry. It is for the same reason that we at Harvey Mudd College have introduced kinetic experiments at all levels from the freshman year on.

What is needed now are further reactions which illustrate, as clearly as the methylene blue, the various aspects of mechanisms. Particularly needed are some reactions whose rates can be readily measured, for which he rate equation can be directly determined, and for which it is obvious that the rate equation and the equation for the net reaction are unrelated in any simple fashion. The usual rate experiments (such as the iodine clock, hydrogen peroxide decomposition, inversion of sucrose) do not, unfortunately, meet these criteria. Even the reaction between silver ion and formate ion has the unfortunate property of possessing a rate equation which corresponds ostensibly to the equation for the net reaction. There are, of course, reactions known which do not have these drawbacks, but a larger number need to get into the literature of undergraduate experiments, and it is hoped that those knowing such experiments will see that this happens.

The field of reaction rates and mechanisms is far too important to be slighted in the future as it has been in the past. Experiments can be done, even in a first course in chemistry, which are intelligible to the student and which clearly point out the real effects of concentration and temperature. The complicated series of steps—with each step simple—which give the overall mechanism and the relationship of the reaction mechanism to the equilibrium state can also be deduced from experimental data. "Kinetics—Early and Often," ought to produce interesting results in the education of future chemists.

A Course in Kinetics Based on Elementary Processes

Chemical kinetics is of importance as a scientific discipline primarily because kinetic data are of major importance in elucidating the detailed mechanisms of chemical reactions and other molecular processes. These mechanisms are often fairly complex, but they are generally described in terms of *elementary processes* that are unimolecular, bimolecular, or (occasionally) termolecular and that take place in single steps.

During the past few years, I have been teaching a course on kinetics in solution, giving three lectures a week during the ten weeks of the spring term. The students are mostly seniors and first year graduate students who have had physical chemistry. The course has been aimed at giving the students an understanding of present theories of chemical reactions and of how experimental observations can be used to obtain information of mechanistic utility. The understanding of elementary processes has seemed to offer the best foundation on which to build the subsequent details.

The course first considers the theoretical treatment of elementary processes and the ways in which rates of these processes are affected by altering such factors as temperature, pressure, solvent, etc.

This detailed discussion of elementary processes provides a foundation for the subsequent consideration of the rates to be anticipated when reactions take place by complex combinations of such processes. The treatment is aided by keeping attention fixed on the instantaneous *rate* of reaction under specified conditions rather than considering integrated extents of reaction. Although integrated rate equations for simple empirical orders often play a considerable part in the teaching of kinetics, they are applicable to a fairly limited number of real reactions and give a rather restricted idea of the problems encountered by a practicing kineticist.

The course then leaves consideration of what the rate of reaction will be for different mechanisms and considers the reverse problem of gathering kinetic data and using them to draw mechanistic inferences. Although this arrangement delays consideration of the type of material with which an experimental kineticist actually deals, it provides a background that permits a more thorough discussion than is possible if treatment of data is introduced before the students appreciate the mechanistic complexities that can arise in practice.

The following outline does not develop the treatment in detail, but it will illustrate a few points and provide an idea of the type of argument. It is hoped that a book covering this material will be ready for publication in the not too distant future.

Introduction and Definitions

A chemical reaction can be represented by the balanced equation

$$aA + bB \rightarrow cC + dD \qquad (1)$$

where the capital letters are chemical species and the lower case letters are stoichiometric coefficients.

The *rate of reaction*, v, is defined to refer to the equation *as written*. Thus, for equation (1)

$$v = -\frac{1}{a}\frac{d[A]}{dt} = -\frac{1}{b}\frac{d[B]}{dt} = \frac{1}{c}\frac{d[C]}{dt} = \frac{1}{d}\frac{d[D]}{dt} \qquad (2)$$

For *some* reactions, the rate can be described over a range of concentrations by an equation of the form

$$v = k_{ex}[A]^{\alpha}[B]^{\beta}[C]^{\gamma}[D]^{\delta}[P]^{\pi} \qquad (3)$$

where the exponents are empirical *orders* that may be positive, negative, zero, integral, or non-integral and may or may not bear any relation to the stoichiometric coefficients of equation (1). The species P in equation 3 does not enter equation (1) at all. The *experimental rate constant*, k_{ex}, is an empirical quantity to be distinguished from the rate constants of elementary processes that are inferred from experimental data by assuming a mechanism for the overall process.

Any experimental rate constant should always refer to the v for a specified chemical equation like (1) and not to a multiple or fraction of that v. Failure of some polymer chemists to relate termination rate constants to the rates of the assumed elementary processes has seriously confused the literature of radical polymerization.

Theoretical Treatment of Elementary Processes

Collisional theories assuming equilibrium distributions. The usual kinetic equations can be derived from equilibrium radial distribution functions and rates of relative motion of molecules. The treatment can be extended to the situation in which the energy of several square terms can contribute to the activation needed.

Statistical thermodynamic theories. Populations of equilibrium energy states provide a basis for deriving the equations originally developed by Glasstone, Laidler and Eyring (*1*).

Theories for very fast reactions. Both collisional and statistical thermodynamic treatments assume that distributions of molecules in space satisfy functions derived for equilibrium. These assumptions fail for very reactive species in solution. The treatment employed has been developed elsewhere (*2*). If the course were not specifically restricted to solution kinetics, it might be appropriate at this point to discuss unimolec-

Presented as part of the Symposium on Kinetics in the Undergraduate Curriculum before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

Digitized by Arya Samaj Foundation Chennai and eGangotri

ular gas reactions in which the equilibrium spatial distributions of internal energy levels are not maintained.

Effects of Controllable Factors on Rates of Elementary Processes

Concentration. Rates in ideal solutions can be treated easily. Statistical thermodynamic theories can be used to derive the equation

$$k = k_0 \, \gamma_A \gamma_B / \gamma^{\neq} \tag{4}$$

where k_0 is the rate constant in ideal solution and the γ's are activity coefficients if species A and B react to form a transition state.

Temperature. Standard equations are easily derivable for activation energy and related quantities.

Pressure. Volume of activation is defined and discussed.

Inert electrolyte. Debye-Hückel expressions for activity coefficients are used to predict effects of changes in ionic strength on rates of elementary processes involving ions.

Dielectric constant. Easily derivable equations predict effects of varying dielectric constant on ion-ion and dipole-dipole reactions. Students are warned that dielectric saturation effects make these equations of marginal value if macroscopic dielectric constants are employed. They are also warned against the dangers of using these equations to interpret effects when dielectric constants are changed by varying the relative amounts of solvent components.

Viscosity. This property has direct influence only on the rates of reactions so fast that equilibrium spatial distributions are not maintained.

Other solvent effects. Solvent media influence rates in many ways that are not yet satisfactorily characterized. Attempts have been made to define properties like nucleophilicity, ionizing power, etc. that have been proposed to characterize solvents.

Isotopic substitution. Rate of reaction may be affected by isotopic substitution of a species that is transferred during the elementary process. Usually smaller effects follow substitution elsewhere in the reactant or in the solvent. Rigorous treatment requires detailed understanding of molecular vibrations.

Molecular Structure. The subject is too broad for general treatment. The brief discussion in this course includes effects of substituents on rates of reactions in aromatic systems.

Kinetics of Consecutive Processes

A consecutive process is defined to be of the form

$$\begin{aligned} A + R_1 &\rightleftarrows I_1 + P_1 \\ I_1 + R_1 &\rightleftarrows I_2 + P_2 \\ &\cdots \\ I_{j-1} + R_j &\rightleftarrows I_j + P_j \\ &\cdots \\ I_{n-1} + R_n &\rightleftarrows Q + P_n \end{aligned} \tag{5}$$

where A and the R's are reactants, Q and the P's are products, and the I's are intermediates. The species A, Q, and each of the I's must be chemically distinct from each other and from all of the other species in these equations. If any species occurs as both R and P, it does so only once for each.

Steps are said to be locally equilibrated when their forward and reverse rates are almost equal and to be irreversible when the reverse rate is negligible compared to the forward rate. A step pre-determines subsequent steps if those steps are virtually sure to follow the occurrence of the pre-determining step.

Conditions are then developed for application of the rate-determining step approximation and of the uniform flux sequence of Christiansen (*3*). When neither approximation is applicable, the reaction can sometimes be separated into sequences for which these approximations are valid. The argument is presented in detail in a forthcoming paper (*4*).

Kinetics of Parallel Processes

Parallel processes provide different mechanisms by which the same reactants can go to the same products. A typical example is the oxidation of oxalate ion by manganese(III); transition states having empirical formulas $MnC_2O_4^+$, $Mn(C_2O_4)_2^-$, and $Mn(C_2O_4)_3^{3-}$ can all contribute to the reaction. The total rate in such a system is the sum of the rates due to the individual parallel processes.

Kinetics of Competitive Processes

Competitive processes occur when the same species may react in two or more different ways giving different products. Competition may be for different positions in the same molecule as in reactions of substituted benzene derivatives, it may involve two species attacking the same initial reactant so that the rate of disappearance of the reactant is the sum of the rates of the two reactions, or it may involve competition for an unstable intermediate so that changing concentrations of competing reagents affect the final composition of the products but not the overall rate of reaction. The discussion of competitive processes provides a good point for presenting the distinction between kinetic and thermodynamic control of reaction product composition.

Kinetics of Repetitive Processes

Repetitive processes are those in which an intermediate can undergo a sequence in which the intermediate is regenerated. This sequence is usually in competition with some other reaction that consumes the intermediate. Many examples involve free radical chains.

Topics discussed include effects on the overall kinetics from change in radicals undergoing termination and competition of termination reactions that are first and second order in radicals.

Branched chain reactions are discussed briefly.

Kinetics of Catalytic Processes

In principle, catalytic processes usually belong in the class of consecutive processes already considered. They offer the interesting kinetic feature that some species that appears as both R and P in equation (5) is usually in much smaller concentration than are the chief reacting species. The discussion offers examples, distinguishes specific and general acid catalysis, and mentions a little about enzymes.

Autocatalysis presents a special problem because catalyst is produced as the catalyzed reaction proceeds.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Kinetics of Induced Reactions

A slow reaction having a favorable free energy change can be induced to go more rapidly by the simultaneous occurrence of another irreversible reaction in the same system. Examples discussed include some of the chemistry of chromium and manganese and the use of initiators in free radical polymerization.

Kinetics of Reversible Reactions

When the final position of equilibrium involves measurable concentrations of the initial reactants, the kinetics of forward and reverse processes are related. The relationship does not permit the kinetics in one direction to be uniquely determined from the kinetics in the other, but certain conclusions can be drawn.

The principle of microscopic reversibility also provides a useful touchstone for rejecting certain mechanisms that would otherwise appear plausible.

Experimental Techniques

Conventional kinetic studies in batch systems require temperature control, measurement of time, and a precise and rapid analytical method. When the time scale gets shorter than a few seconds, techniques can involve mixing in continuous flow, stopped flow, or stirred reactors. When the times of interest become too short even for mixing techniques, a system initially at equilibrium can be perturbed by a periodic method such as ultrasonic sound absorption or by a discontinuous change such as temperature jump or flash photolysis (5).

Mathematical Treatment of Data

Since most experimental techniques measure concentrations at specific times, and since rate of reaction is a derivative quantity, many mathematical treatments involve integration of rate equations for comparison with experiment. Other techniques involve getting derivatives of continuous curves approximating experimental observations. Some specific methods have also been developed.

Mechanistic Interpretation of Kinetic Data

Information from concentration dependence. If all subsidiary equilibria are known and if a single rate determining step exists, the concentration dependence can be used to determine the empirical formula of the transition state for that step. Separate terms in the numerator of the rate expression and increase of apparent order with increasing concentration of reactant indicate parallel mechanistic paths for obtaining product. Separate terms in the denominator and decrease of apparent order with increasing concentration of reactant indicate contributions from consecutive steps or unidentified intermediates formed in significant concentration. Fractional orders frequently but not invariably accompany radical chain processes.

Much of modern kinetic work is concerned with demonstrating the existence of intermediates and determining their properties. Although unequivocal evidence for an intermediate can often be obtained by some competitive technique, lack of evidence can only shorten the permissible lifetime of the intermediate but cannot prove its non-existence.

Information from temperature dependence. Activation energies and similar quantities can often be combined with thermochemical information such as bond energies to draw useful mechanistic conclusions.

Information from other factors. Many factors such as pressure, ionic strength, dielectric constant, etc. have been shown above to influence rates of elementary processes. When the rate of a real process is found to be influenced by these factors, mechanistic inferences can often be drawn. They must be drawn carefully as illustrated by the fact that different investigators have reported (apparently correctly in each case) that increasing ionic strength strongly accelerates, strongly decelerates, or scarcely affects the rate of decomposition of oxalate complexes of manganese(III) (6).

1963 Chemistry Listing: Selected Science Books for Secondary Schools

This guide for librarians and science teachers was prepared by the Connecticut Science Teachers Association. The titles chosen are largely of recent copyright and are considered of value for reference and supplementary reading by student and teacher. The advent of new programs in secondary school chemistry (CBA and CHEMS) and the growing prevalence of the advanced-placement chemistry course have received special consideration by the Committee in the selection of titles. Listing is by author and title, coded for suggested use and with brief commentary. Available for $0.25 from CSTA Bibliography Committee, Central Connecticut State College, New Britain, Conn.

Chemical Kinetics in Laboratory and Classroom

Chemical kinetics is a subject of such importance to chemistry that the teaching of it must of necessity permeate the entire curriculum. The student is introduced to rates of reaction in freshman chemistry (or better yet, in high school chemistry). The framework of kinetics is set forth in the usual physical chemistry course. Examples and more elaborate developments are presented in advanced courses on inorganic and organic chemistry. In spite of the ubiquitous nature of this subject, many institutions have found it advisable to supplement the above fare with a further more-or-less intensive helping of kinetics for the undergraduate. In the following I will present the experience at Berkeley in teaching selected aspects of kinetics in an undergraduate laboratory course on inorganic chemistry. Although the examples are chosen from inorganic systems, the methods are generally applicable.

The course consists of a one hour lecture once a week and two laboratory periods of 3 hours each. By no means is the course devoted entirely to kinetics: perhaps 75% of the lectures deal with kinetic problems but only about one-third of the laboratory work, the remainder being concerned with equilibria, stoichiometry, etc. The chief architect of this course was Professor William C. Bray to whom must go the major credit for its successes. Others who have participated in making substantial modifications are Professors Rollefson, Powell, and myself. Professor Powell particularly has influenced the lecture treatment.

The course content concerned with kinetics has practical objectives. The aim is to give the student a working knowledge which will enable him to plan, carry out, and interpret measurements on rates of reaction. It is hoped that the student will develop a clear understanding of kinetics and will learn to apply his knowledge readily whenever he deals with a rate of reaction.

The lectures start with various stratagems for finding the rate law from experimental data. Important in this connection is the proper planning of experiments so that the data can be readly and reliably applied to establishing the rate law. The technique of "flooding" is emphasized because of the simplification it ordinarily produces by reducing the rate equation to a power dependence on a single concentration. The student is shown how the complete rate law may be obtained even though the concentration of the same substance is always kept small in the flooding procedure—a point which invariably gives some difficulty.

For cases where flooding is possible, concentration dependences and rate constants may be obtained readily by (*a*) substitution into the integrated rate law, (*b*) plotting in such a fashion as to yield a straight line (e.g., log (conc.) versus time for a first order reaction), or (*c*) by a Powell plot.[1] Except for refined calculations, it is advantageous to use a plotting method so that all the data are displayed simultaneously. The importance of having an estimate of the experimental uncertainty of the data is stressed, particularly where one plots logarithms or reciprocals of measured quantities.

When flooding is not convenient experimentally, the rate equation is not so readily integrated and the correct rate law can usually be found more easily by use of the differential form. The student is given practice in this procedure by plotting concentration-versus-time data, taking the slopes at intervals, and substituting these values into various assumed rate equations in the differential form until the correct one is found.

Laboratory Experiments

The planning and interpretation discussed in the lectures is put into practice in the laboratory when the student determines the rate law for the following net reaction:

$$H_2O_2 + 3I^- + 2H^+ = I_3^- + 2H_2O$$

The reaction takes place in a few minutes at room temperature with reasonable concentrations and is accompanied by a readily observable color change. The student is instructed to carry out the measurements by preparing in a test tube a standard triiodide solution corresponding to a small fraction reaction of the peroxide, say 10%. He then observes by eye the time for the reaction to proceed this far in another test tube of the same size. By varying the concentrations of the reactants one by one he can find the order with respect to each and thus the form of the rate law.

It is obvious that the method of measurement used here is crude, yet it is intentionally so. The time for a certain per cent reaction may be obtained much more precisely by adding the appropriate amount of thiosulfate at the start of the experiment and observing the sudden appearance of the triiodide color when the H_2O_2-I^- reaction has produced just sufficient triiodide to consume all of the thiosulfate. Our experience in using this latter procedure, however, was that the student centered his attention on the method of detection rather than the rate of reaction under study.

Presented as part of the Symposium on Kinetics in the Undergraduate Curriculum before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

The visual detection of a certain extent of reaction has additional advantages. The student learns that simple observations and particularly visual observations are important and can lead to useful conclusions. In the present case, after a few trials, he has little difficulty in obtaining times for reaction within ±15% of the correct values.

In interpreting the data the differential form of the rate law is used. A doubling of the iodide concentration leads to a halving of the reaction time for the same standard. It is desirable to give the student experience in handling the differential form since he is not apt to get it in the physical chemistry laboratory and because the physical meaning of the mathematical expression is more easily grasped with the differential than with the integrated form of the rate law. The student must think clearly about what to expect when he doubles his initial peroxide concentration but also doubles his blank to correspond to the same fraction reacted.

The student is instructed to determine the hydrogen ion dependence from *ca.* 10^{-5} to *ca.* $0.5M$ H^+. Since the rate law is[2]

$$+\frac{d[I_3^-]}{dt} = k_1[H_2O_2][I^-] + k_2[H_2O_2][I^-][H^+]$$

he undergoes the rewarding experience of interpreting an apparent non-integral concentration dependence.

As an extra experiment the student may elect to measure a heat and entropy of activation.

In another laboratory experiment the student learns something of the nature of steady states through the study of the catalytic decomposition of hydrogen peroxide by the Br^--Br_2 couple.[3] The two reactions bringing about the steady state are

$$2Br^- + H_2O_2 + 2H^+ = Br_2 + 2H_2O$$

$$Br_2 + H_2O_2 = 2Br^- + 2H^+ + O_2$$

The net reaction at the steady state, where the above two rates of reaction are equal, is the sum, i.e.

$$2H_2O_2 = 2H_2O + O_2$$

In qualitative experiments the student first demonstrates that a steady state is approached from either side, i.e., by starting with peroxide and bromide or with peroxide and bromine, both in acidic solution. In quantitative experiments he determines the value of the steady state quotient R which has the form

$$R = \frac{[Br_2]}{[H^+]^2[Br^-]^2}$$

as a consequence of the rate laws for the two reactions. The distinctions between a steady state and an equilibrium are discussed.

In many minor experiments in the laboratory the student encounters reactions which do not occur in a reasonable length of time. He is faced with the two possibilities: the reaction is slow or the equilibrium is unfavorable. In most cases he can decide about the position of the equilibrium through available data on equilibrium constants, free energies, emf's, or heats and entropies.

[2] See for example Liebhafsky, M. A. and Mohammad, A., *J. Am. Chem. Soc.*, **55**, 3977 (1933).

Topics Discussed in Lectures

A substantial section of the lecture material considers what can be deduced about mechanisms from rate laws—and what cannot be deduced. For a simple, single-term rate law the formula of the activated complex corresponds to the stoichiometry of the rate law, plus or minus solvent, provided only a single activated complex controls the rate.[4] From the form alone of such a rate law the existence of equilibria before the rate determining step can be concluded only if one or more of the concentrations has a negative or fractional exponent. Generally the conclusion that there is an equilibrium before the rate determining step does not lead to an unambiguous identification of that equilibrium. The above statements depend on the assumption that a single activated complex controls the rate. When more than one activated complex is involved the interpretation is more complicated.

Basically two complex forms of rate law exist: the multiple term numerator and the multiple term denominator. When concentrations are expressed in terms of actual species present, these two forms have the simple physical interpretations of parallel reactions for the first and non-productive step(s) competing with a productive step for the second. The student is given practice in postulating mechanisms for such cases. The idea of the steady state approximation enters here. Stress is laid on the exact nature of the approximation and the fact that it does not lead to a constant concentration of intermediate.

Chain reactions are considered briefly. Rate laws are derived from mechanisms but the more difficult task of finding mechanisms from rate laws is only mentioned.

At this point the student is assigned a paper in the literature and is required to write a brief criticism of it. The paper chosen contains an unusual number of errors, both fundamental and trivial. For the good students this is a valuable experience in pitting their intellect against that of the authors. For all of the students it serves as an invaluable demonstration of the care which one must exercise in accepting conclusions even though they are in printed form.

The deduction of the reverse rate law from a combination of the forward rate law with the equilibrium expression is carried out along with a discussion of the principle of microscopic reversibility. The ambiguity in the derived rate law is considered and it is shown how the experimental determination of a single parameter for the reverse reaction, such as the exponent of one concentration or the $\Delta H\ddagger$ for the reverse reaction, suffices to remove the ambiguity. It is also pointed out that the removal of this ambiguity gives additional mechanistic information, i.e., the number of reactant molecules disappearing for each activated complex.

Electrolyte effects are considered briefly in terms of the Brønsted equation derived from activated complex theory. Reference is made to useful approximations for estimating activity coefficients of ions outside of the Debye-Hückel region and attention is paid to the uncertainty in such estimates.

[4] There is an unimportant exception to this rule which may occur when two or more intermediates have concentrations proportional to each other or to some power of each other.

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

A discussion is given of the maximum rate possible for a bimolecular reaction in a solvent such as water. The available experimental results are shown to be in substantial agreement with these expectations. The concept of a limiting rate is useful in proving that certain mechanisms cannot possibly account for observed rates, and examples are considered.

It is shown how the rates of dissociation of acids and hydrogen and hydroxide ions ordinarily react with bases and acids at approximately diffusion-controlled rates. Combining these estimated rates with the equilibrium constant for dissociation one has an estimate of the rate constant for dissociation. It is instructive to the student to learn how slowly water dissociates.

A Laboratory Program in Chemical Kinetics

Three years ago a new course entitled chemical kinetics was offered for the first time at Carleton College. The course was offered in the senior year to students who had already taken courses in organic chemistry, analytical chemistry, and thermodynamics. It is the second in a series of three, one-term physical chemistry courses which replaces a one year physical chemistry course. The laboratory work in this course was designed to be something of a bridge between the student-planned research of graduate school and the teacher-planned laboratory exercises typical of much undergraduate laboratory work. It was felt that students should be forced to assume much of the responsibility for planning as well as executing their experiments. Students should be challenged by the task of interpreting raw data without having a handy instruction sheet to tell them what equation to use and when to use it. Above all it was hoped that somehow during the course every student would feel the thrill that is often accompanied by the exclamation "A ha! I have discovered something." It was also expected that the laboratory work would reinforce the ideas developed in the lecture part of the course and provide an opportunity for the students to become familiar with a wide variety of chemical instruments.

The detailed plans for the laboratory work were based on some assumptions or intuitive rules of thumb. Since real experimentation was to be encouraged, ample time for mistakes or rambles down blind alleys should be provided. Unless a student has the freedom to make mistakes, he really has no freedom at all. This concept means that an average experiment will require at least two afternoons of work. In order to ease the shock of weaning the students from teacher planned exercises, a gradual transition should be made starting with fairly detailed instructions and ending with assignments having almost no specific instructions. The emphasis in each experiment should be placed on the discovery of the form of the rate law and its mechanistic implications, rather than just the determination of the numerical value of a rate constant. This means that a student never knows the form of the rate law for a given reaction before he begins experimenting with the reaction. This approach was expected to provide an opportunity for students to learn general methods of data analysis suitable for a variety of kinetic situations as well as to stimulate student interest.

Presented as part of the Symposium on Kinetics in the Undergraduate Curriculum before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

Assigned Experiments

The first reaction studied in the course is the familiar alkaline hydrolysis of ethyl acetate.

$$CH_3COOC_2H_5 + OH^- = CH_3COO^- + C_2H_5OH$$

Considerable help in the way of detailed instruction is provided the student in this experiment. For example it is suggested that he first check to see if the reaction follows a one term rate law of the form

$$\frac{d[OH^-]}{dt} = k[OH^-]^m[EtAc]^n$$

He is further instructed to run his first experiment with stoichiometric quantities of reactants so the rate law will be simplified to the form

$$\frac{d[OH^-]}{dt} = k[OH^-]^{m+n}$$

To make life really easy for the student, a detailed procedure for carrying out this first, stiochiometric

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

experiment is provided. This procedure includes the amounts and concentrations of all reagents, sampling procedures, and the analytical method to be used in determining the hydroxide concentration in each aliquot.

There are still a few details left for the student to work out. He must decide what mathematical technique should be used to analyze the results of the stoichiometric experiment and so determine k and the quantity $m + n$. He might decide to use the technique developed by Powell of plotting per cent reaction versus log t (*1*), or he might check each of the integrated forms of the rate law graphically or analytically. The student is also asked to design and carry out a second experiment to allow the determination of m and n individually. This might be done by changing the concentration of only one of the reactants in the second experiment and comparing the initial rates of the first and second experiments. Or, an experiment could be designed in which the general second order integrated rate law could be used to analyze the data. The actual experimental procedure to be followed in the second reaction need only be slightly different from that used in the first experiment.

Two afternoons of laboratory work are required by a team of two students for the completion of this problem. Stock solutions of all reagents as well as standardized solutions of all analytical reagents are provided for the experiment. This policy is followed as far as is possible for all experiments in the course.

The hydrolysis of ethyl acetate is an appropriate reaction to begin the course for several reasons. It is simple and straightforward from a kinetic point of view, the analytical procedure used to follow the reaction is simple and familiar, and the species involved in the reaction are familiar. These considerations of familiarity allow the student to concentrate on understanding the kinetic techniques and ideas.

The second experiment is a study of the following reaction (*2*).

Again the student is given a considerable amount of help in planning the experiment, but a little more effort is demanded from him than in the ethyl acetate experiment. It is suggested to the student that the technique of flooding be used in his first experiment with the initial concentration of the piperidine much greater than twice the initial concentration of the 2,4-dinitrochlorobenzene. If the reaction can be described by a one term rate law, its rate law should have the form

$$\text{rate} = k\,[\text{2,4-dinitrochlorobenzene}]^m[\text{piperidine}]^n$$

which simplifies under conditions of excess piperidine to

$$\text{rate} = k_{ps}\,[\text{2,4-dinitrochlorobenzene}]^m$$

where k_{ps} is a pseudo rate constant related to the true rate constant by the following equation.

$$k_{ps} = k\,[\text{piperidine}]^n$$

Complete details for carrying out an experiment under conditions of excess piperidine are provided for the student. These instructions provide for a spectrophotometric determination of 2,4-dinitrophenylpiperidine in quenched aliquots.

As in the hydrolysis experiment the student is asked to decide what mathematical approach should be used to analyze the data from the experiment with the excess piperidine. He is then asked to design and conduct a second experiment which will allow the determination of the order with respect to the piperidine. Most students choose one of three approaches. Some attempt to carry out a reaction with the 2,4-dinitrochlorobenzene in excess and they immediately run into trouble because it is not soluble enough in the ethanol used as the solvent for the reaction. Others choose to use stoichiometric conditions and have trouble with too intense coloration of the product and sometimes too rapid a reaction. The best choice is to keep the piperidine in excess but change its initial concentration from that of the first experiment. This allows determination of a second pseudo rate constant, k'_{ps}. The following two simultaneous equations can be set up and solved for k and n.

$$k_{ps} = k[\text{piperidine}]^n$$
$$k'_{ps} = k[\text{piperidine}]'^n$$

The students' woes are not over. He is now asked to design and carry out an experiment to verify the results he has obtained so far; but this is to be done by taking aliquots, quenching, and determining the chloride concentration in each aliquot by a potentiometric titration. In order to get enough chloride for accurate analysis, completely different conditions must be used than were used in the first part of the experiment.

As a final task, the student is asked to design and carry out an experiment which will allow the calculation of $\Delta H\ddagger$ and $\Delta S\ddagger$.

In the interpretation of his results the student is asked to propose a mechanism which would account for the fact that the rate law is first order in each reactant while the stoichiometry of the equation calls for two molecules of piperidine to react with each molecule of 2,4-dinitrochlorobenzene.

This reaction is highly satisfactory from a number of points of view. It allows the very important technique of flooding to be used, it can be studied by a variety of analytical methods, it illustrates that the form of the rate law cannot be predicted from the stoichiometry, and it goes to completion. Besides all of this, it works well.

As an exercise in thinking and as a relief from the demands of careful, quantitative experimental work, the students have usually been asked to spend an afternoon with test tubes and graduated cylinders studying the iodate-hydrogen sulfite clock reaction (*3*). The reaction is carried out in acid solution in the presence of starch with an excess of iodate. It proceeds according to the following equation until all of the hydrogen sulfite has reacted.

$$IO_3^- + 3HSO_3^- = I^- + 3SO_4^{2-} + 3H^+$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

After all the hydrogen sulfite has reacted, I^0 appears and is detected by the abrupt appearance of a blue-black color caused by the formation of the starch-iodine complex. Students never cease to be amazed to discover that increasing the hydrogen sulfite concentration decreases the time required for all of the hydrogen sulfite to react. The solution to this riddle makes an excellent problem for seniors, but the existence of the riddle makes this a poor reaction for freshman chemistry demonstrations.

After the clock reaction, different experiments have been done during each of the three years that the course has been offered. These experiments have included the following: a polarographic study of the hydrolysis of hexachloroantimonate(V) (*4*), a conductometric study of the alkaline hydrolysis of methylbenzoate and related compounds as an illustration of the use of the Hammett equation (*5*), the determination and interpretation of $\Delta H\ddagger$ and $\Delta S\ddagger$ for the reaction of bromoacetate and thiosulfate (*6*), and a test of the Brønsted equation for the prediction of ionic strength effects on the oxidation of hexaaquochromium(III) by peroxydisulfate (*7*). Not more than one or two of these experiments have been done by any single pair of students. It is hoped that in future years experiments can be developed which will deal with very fast reactions, gas phase reactions, and the use of radioactive tracer techniques.

Independent Work

The last part of the course is used for an independent study in which the students must plan all aspects of the work with very little help from the instructor. Each team of students is expected to choose a general experimental approach, decide on the analytical methods to be used, work out the proper concentration range so that the reaction is neither too fast nor too slow, and take care of all the other details which must be considered in planning a kinetic investigation. The study of the reaction of hydrogen peroxide and iodide in acid solution is an excellent subject for such work (*8*).

$$2H^+ + H_2O_2 + 3I^- = I_3^- + 2H_2O$$

The kinetics of this reaction can be studied in several ways using different analytical procedures. The rate law for the reaction has two terms so it is sufficiently puzzling to provide a challenge to the best of students. As an alternative to working on this problem students have sometimes worked on unsolved problems of their own choosing. These problems have usually developed from suggestions made by the instructor. They have ranged from an attempt to determine the mechanism for the decomposition of

in acid solution to the development of an experiment suitable for use in the freshman chemistry course based on the reduction of thiocyanatoiron(III) by tin(II). Care must be exercised in choosing problems for this kind of independent work. It is not necessary that the problem be completely worked out in this period of time, and indeed, it is not very often that this is done. It is important that the students do not become so bogged down with severe analytical problems, or hopelessly complex kinetic situations that no progress at all can be made toward discovering the rate law.

Student reaction to this course has been most gratifying, especially after the course has been completed. None of the students who have taken the course have avoided periods of frustration and exhaustion, but on the other hand, all of them have experienced moments of elation when all the pieces of the puzzle seemed to fit together. The achievement of being able to plan an experiment and work out the problems involved in its execution gave almost all of the students a feeling of real satisfaction.

The basic purpose of this laboratory program is to provide an opportunity for advanced chemistry students to become involved with the planning and interpretation of experimental work. Chemical kinetics is a particularly appropriate setting for such work for two reasons. First, the experimental work can be conducted without the use of difficult or time consuming experimental methods. Secondly, a minimal theoretical background is required to design and interpret the kind of kinetic experiments discussed here. When a student is asked to do laboratory work requiring considerable theoretical background or difficult experimental techniques, he has all he can do to understand his instructions much less plan new work in the field himself.

In summary, the laboratory program described here consists of a series of four or five experiments. In all experiments the student is faced with the problem of determining a rate law. In the first experiment, the hydrolysis of ethyl acetate, the student does only a small amount of the planning. In the second experiment, the reaction of piperidine and 2,4-dinitrochlorobenzene, he must do more planning; and finally, he is asked to study the kinetics of a reaction with no help at all. The experiments done in the course are not distinctive and are undoubtably done at many colleges. We feel that the involvement of the students in experimental design is somewhat distinctive and has resulted in a stimulating and interesting course.

Acknowledgement

Dr. William Child of Carleton College has made important contributions in the development of this course. He taught the course during the past year and designed several of the experiments.

Absorption, Dispersion, Circular Dichroism, and Rotary Dispersion

One of the great accomplishments of science has been to demonstrate the underlying unity among various superficially different phenomena. One of the aims of teaching science should be to point out this unity whenever possible. The purpose of this paper is to indicate a neglected opportunity to do just this in elementary physical chemistry. The topics to be discussed are light absorption, dispersion, circular dichroism, and rotatory dispersion. These very closely related phenomena are all of importance in chemistry and yet, to the writer's knowledge, no elementary physical chemistry texts discuss them as a unified topic. This is especially unfortunate since on a phenomenological level it could be very easily done.

Absorption and Dispersion

Let us first consider the relationships between ordinary light absorption and dispersion[1] measurements. If the dispersion curve and absorption spectrum of a compound with a weak absorption band are compared, there will be no apparent relationship between them. For example Figure 1 shows such curves for cyclohexanone which has a very weak absorption band near 290 mμ (*1*). The dispersion curve rises monotonically on going to shorter wavelengths, apparently even in the vicinity of the absorption band.

Figure 1. Absorption and dispersion curves for cyclohexanone. Redrawn from Allsopp (*1*).

On the other hand if the same type of curves are compared for compounds having a strong absorption band, there is clearly a relationship. For example Figure 2 shows the absorption and dispersion curves for the strongly absorbing permanganate ion (*2*).

Figure 2. Absorption and dispersion curves for aqueous potassium permanganate. Redrawn from Taylor and Glover (*2*).

This is an example of a general phenomenon which is well understood in both classical and wave mechanical terms (*3*). Figure 3 shows the behavior to be expected with the idealization that the index of refraction is determined by a single absorption, and that the conversion of radiant energy to heat follows a simple law. There are several points to be noted in this figure. First, the dispersion curve rises on going to shorter wavelengths, i.e., this part of it is a "normal" dispersion curve. Second, in the absorbing region the dispersion curve falls on going toward shorter wavelengths, and therefore, this portion of it is called an "anomalous" dispersion curve. Third, in the middle of the absorption band the refractive index becomes equal to its value in a vacuum and at still shorter wavelengths it can actually become less than unity.[2]

A very important aspect of this relationship between absorption and dispersion is that a strong absorption band will always give rise to a large anomaleus dispersion and a weak absorption a small anomaly. This

This research was supported by a United States Public Health Service grant.

[1] A graph of refractive index versus wavelength is called a dispersion curve, because it indicates how light of various wave lengths would be dispersed by a prism of the material being studied.

[2] This means that the velocity of light is greater than in a vacuum which is an apparent violation of relativity theory; but this velocity is the *phase* velocity, whereas relativity theory is concerned with the group velocity.

means then that in the case of the data shown in Figure 1, if extremely accurate measurements were made, a small wiggle should be found in the dispersion curve near the weak absorption band. (There is actually a small break in Allsopp's data but it is not easily seen on the scale used in the present drawing.)

As would be expected, it is possible to develop theoretical relationships between these curves and thus to calculate one curve from the other. These are the Kronig-Kramers equations. It is also possible to discuss these relationships very nicely qualitatively or quantitatively in terms of a simple damped harmonic oscillator model. In order not to detract from the basic simplicity of the phenomenological relations, a further discussion of the physical origin of the absorption-dispersion relationships, together with pertinent references, is included in the appendix.

Figure 3. Theoretical absorption and dispersion curves.

Before our discussion of the analogous relationships between circular dichroism and rotatory dispersion a few additional important features of the absorption-dispersion curves will be considered. One very striking difference is that the absorption phenomenon is exhibited over a relatively small wavelength region but the dispersion manifests itself at wavelengths very far removed from the absorption band. This can be turned to advantage for chemical studies. For example, it is sometimes convenient to determine concentrations of solutions or the purity of compounds having absorption bands in the ultraviolet by measuring their refractive indexes in the visible region. Furthermore, it should be clear that since the dispersion and absorption curves are related, it might be possible to use refractive index measurements in the visible as aids in molecular structure determinations just as absorption spectra are often used. Thus an unsaturated compound with an absorption band in the near ultraviolet could be recognized not only by the *absorption* characteristics of this band but also by the increase in refractive index in the visible compared to a similar saturated compound lacking the absorption band. In the terminology used in this type of study it would be said that the unsaturation causes an "exaltation" of the refractive index. By using the Sellmeier relationship (*3*) between refractive index and wavelength, it might even be possible on occasion to estimate the location of the absorption bands. But now the manifestation of dispersion effects over large wavelength regions can become troublesome, because it is difficult to separate contributions from distant, strongly absorbing bands. For this reason it is more desirable (and much simpler) to measure the absorption bands directly with an ultraviolet spectrophotometer. Since these are now so commonly available, neither the qualitative nor quantitative applications of refractive index measurements are as important as they once were.

Circular Dichroism and Rotatory Dispersion

Until now in the discussion it has not been crucially important to specify whether or not we are considering measurements made with unpolarized or polarized light. We will now consider different effects which arise from using polarized light and will show that "circular dichroism" and "rotatory dispersion" are absorption and dispersion phenomena analogous to ordinary absorption and dispersion.

There are two types of polarization which will be discussed. These are plane and circular polarization. Plane polarized light has its electric vector vibrating in

Figure 4. Top, theoretical absorption and dispersion curves measured with left and right handed circular light. Bottom, difference curves for a compound exhibiting anomalous rotatory dispersion and circular dichroism.

one plane, while the electric vector of circular light rotates as the light beam advances. The vector can rotate clockwise or counter-clockwise (as observed when facing the light source) and the light is said to be right- or left-handed circularly polarized respectively. (The appendix contains a brief description of the relationships among various types of polarized light and the methods used to produce polarization.)

The upper graphs of Figure 4 show the results of a typical dispersion and absorption measurement using left- and right-handed circular light. The results are clearly very similar. In fact unless the compound studied is optically active the two sets of data will be

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

identical to the same measurements made on a gaseous or dissolved material with unpolarized light. But, if an optically active compound is studied, there will be very small but important differences between these curves. When a substance has a difference in its refractive index for right and left handed light, it is said to exhibit "circular birefringence." As discussed in the appendix, this leads to what is commonly described as "optical activity." By analogy with ordinary dispersion, a curve showing the wavelength dependence of circular birefringence is called a "rotatory dispersion curve." When a substance *absorbs* right- and left-handed light differently, it is said to exhibit "circular dichroism." This name is used because the original studies of circular dichroism were made in the visible and it was found that when viewed by transmitted right- and left-handed light a solution of such a substance would be colored differently. A curve showing the wavelength dependence is called a circular dichroism spectrum.

The difference curves for refractive index and absorptivity are shown in the two small graphs at the bottom of Figure 4. The lower graphs were deliberately made smaller to emphasize the fact that the differences *are* small. For example, the differences between two refractive index curves are usually in the sixth decimal place! The differences in the absorption curves will commonly be about one hundreth as large as the absorption curves themselves (though they can be as large as 10% in favorable cases). Figure 5 shows

Figure 5. Absorption, rotatory dispersion and circular dichroism of camphor in hexane. Redrawn from Kuhn and Gorge (*4*).

some data for camphor as an illustration of the relationships among ordinary absorption, circular dichroism and rotatory dispersion (*4*). In this case measurements of rotatory dispersion were made through the entire band because the carbonyl group has a large rotation associated with this weak absorption. (The circular dichroism is not centered in the absorption band as it should be according to the simpler theories relating the two, but the reason for this is now understood (*5*).)

Many of the comments made earlier about ordinary dispersion curves also apply to rotatory dispersion. For example the optical activity of most compounds increases on going to shorter wavelengths because they have optically active absorption bands in the ultraviolet. For this reason, when a rotatory dispersion curve rises on going toward shorter wavelengths it is said to show "normal" dispersion. Near the optically active absorption band the dispersion curve falls with a decrease in wavelength so it is said to exhibit "anomalous" dispersion. In the middle of the absorption band the optical activity commonly goes to zero, and at shorter wavelengths changes sign. The name given to this combined phenomenon of anomalous rotatory dispersion and circular dichroism in an absorption band is the Cotton effect (*6*).

Thus far the analogies between ordinary absorption and dispersion, and circular dichroism and rotatory dispersion have been emphasized. But there is one difference of great practical and theoretical importance. With ordinary dispersion a large absorption band leads to a large anomalous dispersion. A small absorption band can only give a small anomalous dispersion. This is not true with the circular analogues. A strong absorption band may or may not give a large anomaly in the rotatory dispersion while a small absorption band may actually give rise to a moderately large anomalous dispersion. (Compare for example the almost nonexistent anomalous dispersion of cyclohexanone in Figure 1 with the large anomalous rotatory dispersion of Figure 5 which is caused by the same carbonyl chromophore.) One of the consequences of this is that if an optically active substance has a small rotation associated with a strong absorption band, it will be either difficult—or impossible—to make rotatory dispersion measurements through the absorption band because of insufficient light transmission. (For this reason during recent years considerable effort has been made to design more sensitive polarimeters. One has now been built with a sensitivity of approximately 10^{-5} degrees (*7*).)

Again, just as with ordinary dispersion and absorption data, theoretical relationships (the Kronig-Kramers equations) exist between circular dichroism and rotatory dispersion which permit calculating one curve from the other (*8*). This means that in principle no additional information can be obtained about a molecule by measuring both its rotatory dispersion and circular dichroism spectra.

However, there are practical considerations which sometimes make it advantageous to measure one or the other. These considerations parallel the ones discussed for ordinary dispersion and absorption. For example the rotatory dispersion of a molecule can be measured a long ways from the optically active absorption band causing it. Such measurements in the visible region can be used to determine concentrations, optical purity, rates of reaction, etc., but basically what is being studied is the circular dichroism of an absorption band at a shorter wavelength.

When it is not possible to make measurements of rotatory dispersion through absorption bands, it is still possible to estimate the wavelength of the circular dichroism band by fitting the data to a Drude equation. This is analogous to using the Sellmeier equation for locating absorption bands with ordinary dispersion

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

data and it suffers from the same drawbacks, viz., that it is difficult to separate contributions from even rather distant bands. At the present time it is a simple matter to locate ordinary absorption bands with a spectrophotometer. Until recently, however, it was not possible to readily measure the circular dichroism spectrum, especially in the ultraviolet; but at least one commercial instrument is now available which will do this. This promises to be very useful since it will permit the independent examination of the circular dichroism bands of molecules with several optically active chromophores.

Conclusion

This now completes the brief discussion of the relationships among absorption, dispersion, circular dichroism, and rotatory dispersion. These relations and analogies are very simple, provided that only the phenomena themselves are considered and not their underlying causes. The author feels that the unified view this provides for these four superficially unrelated phenomena is very valuable. If, for example, the relationships between circular dichroism and rotatory dispersion were taught in all physical chemistry courses 50 years ago, would as much effort have been largely wasted by chemists on the interpretation of the optical activity of molecules at the sodium *D* line? The author believes that a clearer understanding of these relationships would have hastened the development of methods for measuring both circular dichroism and rotatory dispersion in the ultraviolet.

In order not to obscure the basic simplicity of the relationships already discussed a number of related topics will be considered in an appendix. The individual topics will be only briefly considered and references indicated for additional information.

Applications to chemical problems have only been touched on since they are covered in great detail elsewhere. Weissberger's "Physical Methods of Organic Chemistry" has one chapter devoted to refractometry (*9*) and the interpretation of refractive index and dispersion data. There are a very large number of excellent books devoted to absorption spectrophotometry (*10*, *11*). Applications of rotatory dispersion measurements are covered in some detail in a recent monograph (*8*), and similar applications can be made of circular dichroism spectra. This book also includes a very clearly written chapter by Moscowitz on the relationships between rotatory dispersion and circular dichroism. A partial summary of the early experimental and theoretical work on circular dichroism and rotatory dispersion was recently published by a pioneer in this field, W. Kuhn (*12*).

Appendix

Elliptical, Circular, and Plane Polarized Light. As judged by an observer stationed at some point along an advancing light beam the electric vector of *plane* polarized light oscillates in one plane in a sinusoidal manner. *Circularly* polarized light has a *rotating* electric vector of constant magnitude. Thus the projection of the tip of the electric vector of circular light onto a plane perpendicular to the direction of propagation will give a circle. A third, more general type of polarization, is elliptical polarization. In this case the projection of the vector tip will give an ellipse.

There are many relationships among these types of polarized light but only those of importance for this article will be mentioned. First, a plane polarized beam can be conceptually (and literally) resolved into right- and left-handed circular light components of equal magnitude. Second, if there is a phase shift between the two circular components this is equivalent to rotating the plane of polarization. And third, if there is a change of magnitude of one circular component relative to the other, elliptical light will result.

Figure 6. The circular components of light in various states of polarization; see text. The light beam is advancing toward the observer.

These three statements can be graphically demonstrated by reference to Figure 6. Figure 6*a*–*c* represent the resolution of plane polarized light with an electric vector E_p into circular components with rotating vectors E_r and E_l. The first three drawings indicate the appearance of the two circular and the one resultant linear component at a particular point in space at three different times. Notice in Figure 6*b* that the E_r and E_l vectors cancel one another at one point in the cycle. If there is a phase shift of one circular vector with respect to the other, this will lead to a rotation of the plane of polarization of E_p as shown in Figure 6*d*. If one circular component is reduced in magnitude relative to the other (as when a plane polarized beam passes through a solution exhibiting circular dichroism), the light will become elliptical as in Figure 6*e*, *f*. Notice that in this case there is no position comparable to Figure 6*b* in which cancellation occurs, so the resulting light cannot be plane polarized. Furthermore, since the magnitude of the *resultant* changes with time (compare Figure 6*e* and 6*f*), it cannot be circular light.

Production of Circular Light. Circular light can be produced by passing plane polarized light through an optical device known as a quarter wave plate. The quarter wave plate is made of a material having along two axes two different refractive indexes for plane polarized light. A light beam with a plane of polarization incident at ±45° to these axes will emerge from the plate with two orthogonal components traveling in the same direction, but with a quarter wave phase difference between them. The resultant of two such waves is a circularly polarized wave of either right- or left-handedness, depending on whether the orientation of incident light vector is plus or minus 45° to the axes. A typical quarter wave plate is a thin sheet of mica.

For a very lucid introductory discussion of the properties of polarized light the reader is referred to "Optics" by F. W. Sears (*13*). (Notice in particular Figures 7–16, 17, and 23 of this reference.) A more complete treatment of these topics can be found in any advanced level optics text (*3*).

Measurement of Rotatory Dispersion and Circular Dichroism. Since optical activity is observed in any substance with a difference in refractive index for right and left handed circular light, it should be possible to measure this directly with a refractometer. For example, a Rayleigh interferometer could be used with a polarizer and quarter wave plate in each beam to measure the refractive index difference directly. However, the difference in refractive index is too small to make this a useful method. On the other hand, it turns out that the small difference can easily be measured indirectly by using a polarimeter which measures the rotation of the plane of polarization resulting from the phase shift between the right- and left-handed circular components of the plane polarized beam entering the sample. (In recent years there have been remarkable improvements in polarimetry. For examples see references (*7*) and (*14*).)

Circular dichroism can also be measured directly or indirectly. For direct measurements, polarizers and quarter wave plates (giving right- and left-handed circular light) could be inserted in the beams of a double beam spectrophotometer and the difference in absorbance measured with the same circularly dichroic sample in both beams. There are practical difficulties in such a direct measurement but recently a commercial instrument has been produced which does measure dichroism directly. For the principle of its operation see Legrand and Grosjean (*15*). In the discussion of Figure 6*e* it was pointed out that circular dichroism leads to the production of elliptical light. By using a quarter wave plate in an appropriate manner it is possible to make an "ellipsometer" which will measure the ellipticity of light (and therefore, indirectly the circular dichroism of a sample (*16*)).

Physical Origin of the Absorption-Dispersion Relationships. When the relationships between absorption and dispersion were first discovered, explanations were proposed by analogy with the behavior of a damped harmonic oscillator. If such an oscillator is forced into motion by a force varying sinusoidally with time, the power consumption and displacement of the oscillator reach a peak when the frequency of the driving force is equal to the natural resonant frequency of the oscillator. It was proposed that molecules contain atomic or electronic oscillators with natural frequencies of oscillation. When these oscillators are set into motion by a light wave, they consume the maximum power at their resonant frequencies. This then is the origin of an absorption band. The oscillating electrons would also radiate light (since accelerated charged particles radiate), and the interaction of this scattered light with the original light beam leads to the observed dispersion anomalies. A detailed discussion of this point is lengthy but involves no conceptual diffiulties. At a much later date these ideas were reformulated in wave mechanical terms.

A very clear discussion of this problem in both classical and wave mechanical terms can be found in "Quantum Chemistry" by W. Kauzmann (*17*) and in (*10*).

Other Absorption-Dispersion Phenomena. In addition to the two "paired phenomena" discussed in the text there are a number of others of some chemical importance such as absorption-dispersion of the infrared, radio frequencies (electron spin and nuclear magnetic resonance), X-rays, and the Faraday effect. These will now be very briefly considered.

The extension of the text's discussion of absorption-dispersion in the electronic spectral region to the infrared is very obvious. An understanding of infrared absorption-dispersion is useful in discussing the reasons for needing a number of prisms in infrared spectrophotometers to obtain adequate dispersion with reasonable prism transmission.

At still lower (radio) frequencies one can observe electron spin resonance (*18*) and nuclear magnetic resonance (*19*) spectra. Both resonance phenomena exhibit absorption and dispersion modes exactly analogous to the ones already discussed. Just as in the ultraviolet, visible, and infrared regions, radio frequency absorption spectra are more important than dispersion measurements. But there are situations where conditions are more favorable for the latter (*18*).

At very high frequencies, in the X-ray region, absorption-dispersion is also observed. An understanding of this is helpful in studying the technique used by Bijvoet in determining the absolute configuration of tartaric acid (*20*).

The induction of optical activity in a substance by a magnetic field is known as the Faraday effect. It also shows the expected relationships between its magnetic rotatory dispersion and magnetic circular dichroism (*21*). Recently it has been suggested that a study of the anomalous dispersion of the Faraday effect might provide a useful method of identifying singlet-triplet transitions (*22, 23*).

Another example of a paired phenomenon of chemical importance is the dielectric loss factor and the dispersion of the dielectric constant (*24*). Also of importance are the absorption and dispersion of sound (*25*). Sound dispersion measurements have recently been exploited for studying very fast chemical reactions (*26*).

Finally two systems which are useful in discussing the physical basis for the absorption-dispersion phenomena are the damped harmonic oscillator (*17*) and the resonant RLC electrical circuit. A general treatment of the formal mathematical relationships (such as the Kramers-Kronig equations) between all of these paired phenomena can be found in a paper of Macdonald and Brachman (*27*).

A Reaction Vessel for Kinetic Studies below Room Temperature

We are studying some reactions of cobalt complexes of the type

$$Co(NH_3)_5X^{2+} + OH^- \rightarrow Co(NH_3)_5OH^{2+} + X^-$$

which are too rapid to be examined by conventional methods above 10°C under the conditions of immediate interest. As room temperature here approaches 30°C it is difficult to remove aliquots without raising the temperature of the sample. This would introduce large errors since these reactions also have high energies of activation.

We have overcome this problem by use of a piston reactor similar in principle to that first described by Farhat-Aziz and Moelwyn-Hughes.[1] The modified vessel is shown in the drawing. The outer barrel consists of precision bore tubing of 34.5 mm diameter and is about 10 in. in length. About 3 in. of a ground glass piston attached as shown serve as a seal for the plunger. Samples are obtained by opening the stopcock and depressing the plunger. The plunger is divided into two compartments by a glass-partition with the lower compartment evacuated and sealed off to reduce heat transport from one section to the other. The thermostat, in which the reactor is placed, is a water bath which is cooled by circulating liquid at a temperature of 10–20°C below the desired bath temperature. Temperature control is obtained by electrical heating, a mercury thermoregulator, and electronic relay in the usual manner. The cold liquid is also circulated through the upper chamber of the plunger using the inlet and outlet tubes shown. This ensures that the inner tube through which the reacting solution has to pass for sampling, is at a much lower temperature than the thermostat temperature. By wasting a little of the solution prior to sampling the portion of the tube beyond the stopcock is also cooled. The aliquots are therefore cooled during sampling and quenching is completed by collecting the sample in a cold tube containing a small volume of 73% perchloric acid. The small amount of mercury which acts as seal for the piston also prevents any leakage of condensed water from the top of the piston into the vessel. There is no contact between the mercury and the liquid contained below the piston.

Reaction vessel

Acknowledgment is made to Mr. N. Baney for constructing the apparatus.

Textbook Errors, 47

On Hydrogen Bonds

While the precise geometry of hydrogen bonds may appear, at first sight, to be a rather trivial property on which to center attention, it was just such attention to detail which led, for example, to the formulation of protein structures by Pauling and Corey and to the Watson-Crick hypothesis for the structure for DNA. It thus seems important to call attention to examples of errors which are at present being propagated in textbooks.[1] A student can hardly be expected to develop a proper feeling for the geometry of hydrogen bonding if he is presented with impossible structures.

One of these purports to give a partial arrangement of the water molecules in $CuSO_4 \cdot 5H_2O$. The determination of the structure of this compound, by X-ray diffraction[2] found an elongated octahedral coordination for the copper atoms: four H_2O arranged in a square about each Cu^{+2}, with two more distant oxygen atoms of different sulfate ions completing the octahedron. The fifth water molecule bridges two sulfate groups of different $Cu(H_2O)_4^{++}$ complexes. Therefore, to formulate—as has frequently been done—the following complex,

where one water molecule forms two hydrogen bonds to the same sulfate ion, is not only contrary to the crystallographic results but also does violence to the geometrical requirement of a linear, or nearly linear O—H···O system. It is obviously not possible to construct such a complex without introducing an unacceptably large deviation of the angle O—H···O from 180° or without the requirement that the angle H—O—H deviate from a nearly tetrahedral value and to preserve at the same time the characteristic O···O distances of about 2.8 Å.

Another related error involves maleic acid for which the crystal structure known from X-ray diffraction.[3] This structure has been misinterpreted in one textbook as follows, and the error has now found its way into at least one other textbook.

The above formulation in which the two hydroxyl groups point at each other brings the two hydrogen atoms impossibly close to each other and thus is obviously incorrect. The original X-ray study implies the correct formulation:

This may be arrived at by identification of the carbon-oxygen bonds of 1.20 and 1.21 A as the two C=O bonds and those of 1.27_5 and 1.27_5 Å as the two C—OH bonds (the hydrogen atoms were not located directly). One hydroxyl group is involved in intramolecular hydrogen bonding, the other in intermolecular, a result in complete agreement with expectation.

Other examples of geometrically unacceptable hydrogen bonds may easily be found in textbooks, but these are quite often the result of exigencies of typography rather than an incomplete understanding of the geometry of the interactions. For example:

does not represent the correct geometrical situation in ice, where each oxygen atom is tetrahedrally surrounded by four others. This and other examples fall into the same class as do many conventional figures used in texts and journals, such as

for the regular hexagonal benzene ring. In that instance, it is probably not necessary to emphasize the difference between the printed page and reality. A

Suggestions of material suitable for this column and guest columns suitable for publication directly are eagerly solicited. They should be sent with as many details as possible, and particularly with references to modern textbooks to Karol J. Mysels, Department of Chemistry, University of Southern California, Los Angeles 7, California.

[1] Since the purpose of this column is to prevent the spread and continuation of errors and not the evaluation of individual texts, the source of errors discussed will not be cited. The error must occur in at least two independent standard books to be presented.

word of caution in the case of hydrogen bonds, on the other hand, appears to be appropriate.

Digitized by Arya Samaj Foundation Chennai and eGangotri

The question of what the student *should* be taught is readily answered. The concept of a hydrogen bond was first introduced[4] in order to explain some of the anomalous properties of water, acetic acid, ammonium hydroxide, etc., in terms of an interaction between the hydrogen atom of an >N—H, \O—H, or F—H group with an electronegative atom such as fluorine, oxygen, or nitrogen. The properties of such "hydrogen bonds" have since been extensively investigated by numerous methods. This interaction is now considered to be essentially electrostatic in nature, and the conventional symbols N—H···O, O—H···O, and the like, imply two conditions which have, in fact, been amply verified by direct experiment. Direct experiment has shown that the hydrogen atom lies on, or close to, a line joining the two heavier, electronegative atoms, and that it is much closer to one of these atoms than the other, corresponding to a covalent bond on the one hand and the electrostatic interaction on the other.[5] It is probably desirable to emphasize these two conditions when first discussing hydrogen bonded structures. Comprehensive reviews are available[6] in which the various properties of hydrogen bonds are discussed.

[5] So-called "symmetrical" hydrogen bonds, such as F···H···F in KHF_2, and "bifurcated" hydrogen bonds, such as N—H:(O)(O) in nitramide, represent exceptions to the usual behavior, and other examples of these have been only very rarely encountered.

Cyclobutane Chemistry

2. *Reactions and Mechanisms*

The following discussion on synthetic approaches to cyclobutanes is intended to acquaint the reader with the more recent works in this field. For those who are interested in the historical developments of cyclobutane preparations, some lead articles and books are included in reference (*1*) of the previous paper.[1]

Although borderline cases exist, we have attempted to categorize the reactions into free radical (thermal and photochemical) and polar-type cyclizations. Where mechanisms have not been included in the original paper, an effort has been made to propose a possible path of reaction. Moreover, we have limited ourselves to those syntheses which offer most promise with regard to facility and scope of preparation.

Free Radical Cyclizations (Thermal)

Homocyclization of Perhaloethylenes and Cyclization of Perhaloethylenes with Olefins and Acetylenes (*53*). Chlorotrifluoroethylene (I) dimerizes to give a product which is approximately 50-50 *cis* and *trans* 1,2-dichlorohexafluorocyclobutane (II). This thermal cycloaddition is carried out by heating at 180–200°C in an air free, stainless steel autoclave in the presence of a free radical inhibitor to prevent linear polymerization.

Homocyclization occurs easily with compounds of the type $CF_2{=}CX_2$, only if X is halogen. The thermal cyclization of chlorotrifluoroethylene (I), tetrafluoroethylene and 1,1-dichloro-2,2-difluoro-ethylene give 80–90% yields of the cyclobutanes.

Cycloaddition of (I) with acrylonitrile forms 3-cyano-2-chloro-1,1,2-trifluorocyclobutane (III) (*54*).

[1] For the first article of this pair see THIS JOURNAL, 40, 504 (1963). Literature citations are numbered consecutively for the two papers.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

When chlorotrifluoroethylene (I) is treated with phenylacetylene in a sealed tube at 120° for 24 hr, 1,1,2-trifluoro-2-chloro-3-phenylcyclobutene (IV) is formed in yields up to 75% (*55, 56*).

With this group of reactions in mind, one can theorize on the following question: What are the influential factors involved in the direction of addition of unsymmetrical haloethylenes to themselves and to other symmetrical olefins? J. D. Park explains orientation of the reactants on the basis of the most stabilized diradical in the product-determining transition state. For example, in the homocyclization of (I), (I*a*) would be the diradical of lowest energy since the stability of free radicals is governed by the nature of the halogen (i.e., I>Br>Cl>F) (*57*).

The orientation of cycloaddition of these types of olefins can be predicted by assuming a diradical similar to (I*a*) which is most stabilized with respect to such olefin substituents as halogen, nitrile, aromatic, and other electronegative groups.

A concerted rather than a stepwise diradical intermediate has also been proposed in thermal cycloadditions (*58, 59*). This would entail a simultaneous formation of bonds between C-1,3 and C-2,4, eliminating the possibility of free rotation about bonds C-1,2 and C-3,4. The concerted process thereby predicts a stereospecific addition. In view of the fact that a 50:50 *cis-trans* isomer distribution of products was isolated, the stepwise diradical mechanism is favored in this case.

Cycloaddition of Allenes to Olefins (*60*). Thermal cycloaddition of allenes and olefins substituted with nitrile, carboxyl, carboalkoxy, aldehyde, and aryl groups form 3-methylene cyclobutanes. This extends the realm of cycloaddition products to nonfluorinated 1,3 disubstituted cyclobutanes.

When allene is treated with acrylonitrile at 200°, 3-methylene cyclobutane carbonitrile (V) is formed in 60% yield.

Side reactions occur due to the dimerization of allene to 1,2 dimethylenecyclobutane with subsequent addition of acrylonitrile to form the octahydronaphthalene (VI). These side reactions are noticeably diminished when an excess of the olefin portion is employed.

A possible mechanism involves reaction of the central allene carbon with the β carbon atom of acrylonitrile to render the most stabilized diradical. Cyclization follows electron pairing of the diradical (*59*).

Maleic anhydride and allene form the adduct, 3-methylenecyclobutane 1,2-dicarboxylic anhydride (VII). Treatment with alkali and then acid converts the anhydride into 3-methyl-2-cyclobutene-1,2-dicarboxylic acid (VIII) in 84% yield. This latter intermediate is used to prepare a variety of functionally substituted cyclobutenes containing amide, amine, ester, hydroxyl, and nitrile groups (*61*).

Free Radical Cyclizations (Photochemical)

Excellent yields of 2-hydroxycyclobutanones are obtained through photolysis of certain 1,2-diketones (*62*). For instance, when 4,5-octanedione was irradiated in butanal at 30–35° for 23 hr, a 92% yield of 2-hydroxy-3-methyl-2-propylcyclobutanone (IX) was formed. Small amounts of side products, 5-hydroxy-4-octanone (X) 8.7% and 5-oxo-4-octanol butyrate (XI) 7.7% were isolated. When butanal itself

is irradiated, 58% of (X) forms. This series of experiments indicates that there is a high selectivity for cyclobutane formation (i.e., intramolecular reaction) even in a solvent which is competitively reactive toward free radical attack.

However, a preference for reduction and carbonyl addition was reported in the photolysis of 3,4-hexanedione in propanal. In this case intramolecular reaction or cyclobutane formation involves a more unstable primary free radical rather than the more stabilized secondary free radical of the previous 4,5-octanedione cyclization. Hence, only 23% of 2-ethyl-2-hydroxycyclobutanone was formed along with a majority of propanal free radical products, 4-hydroxy-3-hexanone (23%) and 4-oxo-3-hexanol propionate (54%). When 3,4-hexanedione was exposed to sunlight in the more inert solvent, cyclohexane, a 60% yield of the cyclobutanone formed.

These reactions support the proposed mechanism by W. H. Urry for the selective formation of 2-hydroxycyclobutanones. The diradical forms a six-membered cyclic transition state for facile hydrogen atom transfer.

A *trans* structure is suggested in the triplet or single π^* state with double bond character between atoms 2 and 3 and thus coplanarity with the oxygen atoms and carbon atoms 1, 2, 3, and 4. If this were not so then the alternate path, formation of 1-alkanoyl-cyclobutanols, could occur by attainment of a favorable arrangement of carbon atoms 5, 6 and hydrogen 6 with respect to the carbonyl 3 oxygen. No 1-alkanoyl cyclobutanol is isolated in this highly specific reaction.

Polar-Type Cyclizations

Cycloaddition of Enamines with Electrophilic Olefins. Cyclobutanes are formed by the treatment of enamines, which lack β-hydrogen atoms, with electrophilic olefins, such as methyl acrylate and dimethyl maleate (*63, 64*).

A 75% yield of methyl 2-dimethylamino-3,3-dimethyl cyclobutane-carboxylate (XIII) was reported when methyl acrylate and *N,N*-dimethylisobutenylamine (XII) were heated for two hours at 170°. Acrylonitrile, α,β-unsaturated sulfones, and nitro compounds also form cyclobutanes with isobutenylamines. K. C. Brannock has observed that cyclobutanes can be formed with enamines having one β-hydrogen if conditions are mild enough to avoid ring cleavage (*65*).

The orientation observed in formation of (XIII) is outlined below as a polar-type of cycloaddition reaction.

Cycloaddition of Ketenes to Enamines. Hasek and Martin have reported that the reaction of ketene or dialkylketenes with enamines give 3-dialkylamino-cyclobutanones (*66, 67*). Dimethylketene (XIV) and *N,N*-dimethylisobutenylamine (XII) react at room temperature in isopropyl acetate to give a 64% yield of 3-dimethylamino 2,2,4,4-tetramethylcyclobutanone (XV).

When ketene is treated with (XII) in hexane at 0°, 3-dimethylamino-2,2-dimethylcyclobutanone is formed. Upon warming, (XVI) undergoes a ring-opening to give a 93% yield of 1-dimethylamino-4-methyl 1 pentene-3-one (XVII).

Cyclobutanones, such as (XVI), having one or more α-hydrogens are subject to an irreversible ring cleavage, whereas cyclobutanones having no α-hydrogens, such as (XV), are quite stable. Ring cleavage is probably initially induced by the basic amine group which can readily abstract an acidic α-hydrogen. The cyclobutyl carbanion (XVIII) (partially stabilized by the ketone) can then reform into a conjugated enaminoketone with accompanying ring cleavage. The carbanion (XIX) formed from the rupture of the carbon-carbon bond can abstract a proton from another molecule of (XVI) and the chain of events is repeated again.

Opitz has treated *N*-morpholino-isobutene with propionyl chloride in the presence of triethylamine to form 2,2,4-trimethyl-3-morpholino-cyclobutanone. Presumably this reaction proceeds via the *in situ* formation of methyl ketene due to dehydrohalogenation of propionyl chloride by triethylamine. This is followed by cycloaddition of the ketene with the enamine (*68*).

Potassium Catalyzed Dimerization of β-Alkylstyrenes (*69*). When β-methylstyrene (65% *trans*, 35% *cis*) is added to a potassium metal dispersion in methyl

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

cyclohexane at 100°, the products are 50% of recovered β-methylstyrenes and 45% of stereoisomers of 1,3-dimethyl-2,4-diphenylcyclobutane (XX).

XX

The cyclobutane structure is supported by the following evidence:

(1) There was no olefin unsaturation in (XX).
(2) The NMR spectrum showed the presence of CH_3CH and the absence of CH_3CH_2-groups.
(3) On hydrogenolysis (XX) was wholly converted into 1,3-diphenyl-2-methylpentane which was independently synthesized.

The mechanistic path of the dimerization is visualized by Pines as follows:

1. $C_6H_5CH{=}CH\,CH_3 + K \rightarrow R^-K^+$
2. $C_6H_5CH{=}CH\,CH_3 + R^-K^+ \rightarrow C_6H_5CH{=}CH_2{}^-K^+ \leftrightarrow C_6H_5\bar{C}H\,CH{=}CH_2\ (K^+)$

XXI

4. $XXI + C_6H_5CH{=}CHCH_3 \rightarrow XX + C_6H_5CH{=}CHCH_2{}^-K^+$

In step three, stabilization of the primary carbanion is inferred as a result of the strain energy in the cyclobutane. This might be attributed to the overlap of π orbitals of the ring carbon atoms with that of the carbanion, a phenomenon which has been discussed earlier in this review.

Ring Cleavage Reactions

A discussion of cyclobutane chemistry would not be complete if ring cleavage reactions were omitted. It is of extreme importance to the experimentalist to be aware that cleavage reactions can occur readily.

When cyclobutanes are involved in a series of reactions it is of utmost importance to confirm the presence of the intact ring by reference derivatives and NMR studies for each step.

Ease of cleavage will vary with the inherent strain of the cyclobutane, the substituents on the ring, nature of reagents, and the conditions of reaction as indicated in the first section of this review. A cyclobutane may cleave and then reform reversibly, form noncyclic compounds, or cleave and then reform into a different cyclobutane, a cyclopropane, or an enlarged ring. Some recent examples of these types of ring-opening reactions are presented.

An Alkaline Catalyzed Ring Opening of Phenylcyclobutenedione. When phenylcyclobutenedione (XXII) is boiled with a dilute solution of sodium hydroxide in methanol, benzaldehyde and benzylidenepyruvate are formed. An outline of this ring opening mechanism, as proposed by J. D. Roberts, is described below (*70*).

XXII

The base is believed to induce a type of benzilic acid rearrangement to give the cyclopropene intermediate (not isolated). The cyclopropene undergoes ring cleavage to give benzylidenepyruvic acid which is hydrolyzed to benzaldehyde and pyruvic acid in a reverse aldol condensation reaction.

Another possible path to the products is simultaneous ring cleavage of the $C_1 - C_4$ bond with hydroxide ion attack of the carbonyl carbon of phenylcyclobutadiene.

Ring-Opening Reaction of 1,1-Difluoro-2-Chloro-4-Piperidino-3-Phenyl-2-Cyclobutene. Fluorine-substituted phenylcyclobutenes can be converted into the corresponding ketones by treatment with concentrated sulfuric acid at 100°C (*71*).

When this reaction was attempted with 1,1-difluoro-2-chloro-4-piperidino-3-phenyl-2-cyclobutene (XXIII), the ketone was isolated as a hydrate salt (*72*).

XXIII

This salt is partially hydrolyzed to the free base (XXIV) in anhydrous organic solvents and undergoes a thermal ring-opening reaction to form a vinyl ketene intermediate (XXV). This ketene intermediate can be trapped by adding water to form a β, γ-unsaturated acid (XXVI).

XXIV XXV XXVI XXVII

The ethyl ester of the corresponding hydrogenated free γ-amino acid (XXVII) was identical with an authentic sample of ethyl-3-phenyl-4-piperidinobutyrate.

Digitized by Arya Samaj Foundation Chennai and eGangotri

This ring opening is similar to the reversible formation of (1 - phenyl - 2 - chloroethenyl) - chloroketene (XXIX) from 2,4-dichloro-3-phenylcyclobutenone (XXVIII) in chloroform at 100°C (*72, 73*).

Catalytic Hydrogenation and Ring Cleavage by Alcohols. The catalytic hydrogenation of dimethylketene dimer was investigated and found to give cleavage products under certain conditions (*74*).

When (XXX) was hydrogenated in methanol with a ruthenium catalyst, a mixture of *cis* and *trans* (XXXI) was formed.

Hydrogenation of the dimethylketene dimer (XXX) in methanol over Raney nickel gave 1-hydroxy-2,2,4-trimethyl-3-pentanone (XXXIV) and methyl-2,2,4-trimethyl-3-oxovalerate (XXXV). The latter was formed slowly by methanolic cleavage of (XXX). Formation of (XXXV) was accelerated when catalyzed by alkaline reagents. One may propose an S_N2 mechanism to partially explain the increased rate of reaction when a stronger nucleophile is introduced.

It would be of interest to study this reaction without hydrogenation to observe any influence of base alone on this cleavage.

A Nucleophilic-Catalyzed Ring Opening-Ring Closure Sequence. When the dione (XXX) was treated with malononitrile in pyridine solution, *bis*-(dicyanomethylene)- 2,2,4,4-tetramethylcyclobutane (XXXVI) was formed in 97% yield (*75*).

During treatment of (XXXVI) with triethylamine, a rearrangement occurred to give the isomeric 2,2-dicyano-3-isopropylidene-4,4-dimethyldicyanomethylenecyclobutane (XXXVII). A ring cleavage-ring closure sequence catalyzed by a nucleophile is proposed. An attempt to elucidate this mechanism is presented.

A nucleophilic attack by triethylamine cleaves the ring. The carbanion undergoes a resonance shift to form the isopropylidene substitutent and the dicyanomethane carbanion attacks the β carbon atom of the dicyanoethylene group thereby closing the ring.

The Current Prominence of Analytical Chemistry

Analytical chemists in the past have been viewed as a minority group doing very routine work of little significance. Actually, analysts today comprise the second largest portion of the registration of the American Chemical Society. Also, the number of analytical meetings and publications, and the wide circulation of analytical chemical journals indicate the current prominence of this aspect of chemical science.

Chemical and Engineering News (December 11, 1961, p. 123) printed a table showing the distribution of specialties within the ACS membership in 1960.

	Population
Organic chemistry	44.2%
Analytical chemistry	16.2
Physical chemistry	13.4
Biochemistry	9.8
Inorganic chemistry	7.3
Agricultural and food chemistry	5.9
Other	3.2

One quickly notes that analysts are the second largest group in the Society, outnumbering physical and inorganic chemists, and that there is one analyst for about every three organic chemists.

The upsurge in analysis began during or just after World War II with the expansion of the analytical "tool kit." The numerous instrumental devices which have been developed have greatly broadened the scope of analytical potential. In addition, the classical analytical approaches (volumetric, gravimetric, and combustion analysis) have not been lying idle or decaying; these also have been greatly expanded and streamlined.

One can follow the expansion of the analytical field by examining the history and content of the analytical chemical journals. *Analytical Chemistry* was first issued in 1929, a rather recent date. In the 33 years of its existence, it has grown to be second in circulation among ACS publications. The circulation of *Analytical Chemistry* (October, 1962) was larger than the combined circulation of the three next largest.

October, 1962, circulations are:

Industrial and Engineering Chemistry	
Analytical Chemistry	29,613
Journal American Chemical Society	28,999
Journal Organic Chemistry	15,981
Journal Physical Chemistry	7,253
	5,485

The 1929 volume of *Analytical Chemistry* contained approximately 100 papers in 240 pages. The 1961 volume contained 550 papers and 2000 pages. In addition to the growth of this one journal, one can see the establishing of several new publications in the field of analysis: *Talanta, Microchemical Journal* (soon to have a new name), *Analytica Chemica Acta, Journal of Chromatography, Informacion de quimica analytica*, and *Zhurnal Analitiskoi Khimii*. Of course, the older analytical journals also have expanded; these are *The Analyst, Zeitschrift für Analytische Chemie, Microchemie* (*Microchemica Acta*) and *Chemist-Analyst*. It is interesting to note that in 1962 some 2100 papers were published in the field of gas chromatography alone, with over 10,000 papers estimated for the total field of analysis.

The above publication statistics serve to indicate the magnitude of the growth of the analytical field. The scope of the growth is indicated by the diversity of the subjects covered by the papers. In 1929, the papers in *Analytical Chemistry* were involved mainly with gravimetric and volumetric analysis, with some papers on emission spectroscopy, X-ray analysis, and determination of physical constants. There was no Review issue for 1929 since the field was so small. The 1962 Review issue of Analytical Chemistry covers 38 different areas of analytical specialty:

Biochemical Analysis; Chromatography; Electrochromatography; Gas Chromatography; Ion Exchange Chromatography; Distillation Analysis; Electroanalysis and Coulometric Analysis; Extraction; Fluorometric Analysis; Gas Analysis; Instrumentation; Ion Exchange; Inorganic Microchemistry; Organic Microchemistry; Chemical Microscopy; Electron Microscopy; Nucleonics; Polarographic Theory, Instrumentation, and Methodology; Organic Polarography; Emission Spectrometry; Absorption Flame Photometry; Emission Flame Photometry; Infrared Spectrometry; Light Absorption Spectrometry; Mass Spectrometry; Magnetic Resonance Spectrometry; Raman Spectrometry; Ultraviolet Spectrometry; X-Ray Absorption and Emission; Statistical Methods in Chemistry; Differential Thermal Analysis; Titrations in Nonaqueous Solvents; Amperometric Titrations; Potentiometric Titrations; Volumetric and Gravimetric Analytical Methods for Inorganic Compounds; Volumetric and Gravimetric Analytical Methods for Organic Compounds; X-Ray Diffraction; Magnetic Susceptibility.

The growth of the field of analytical chemistry can also be seen from the growth of the number of meetings specifically concerned with analysis.

It is well also to point out that the registered attendance at the Pittsburgh Analytical Symposium has been about 4000 or about one-third that for national ACS Meetings.

The prodigious growth described above can be attributed mainly to the demand by chemical technology for qualitative and quantitative information about the species present in systems. Hence, practically any device or approach capable of measuring a parameter of a chemical system has been quickly adapted for analytical application. The list of specialties quoted from the 1962 Review issue of *Analytical Chemistry* illustrates this point. The growth has been so fast that the demand for analysts and analytical chemists exceeds the supply. As a result, industry has taken many chemists not specifically trained in analysis and allowed them, by direct training or self-training, to become analytical chemists. In my own analytical department there are twelve PhD chemists, of which only six have their degrees in analytical chemistry, three have their degrees in organic chemistry, two in physical chemistry, and one in fuel technology. Of the seven MS men on the staff, three were graduated as analysts, two as physical chemists, one as an inorganic chemist, and one as an organic chemist. This pattern is qualitatively repeated in almost every industrial analytical laboratory. The industrial analytical chemist of any level enjoys the same "status" as his counterparts in synthesis or engineering; he is no longer looked down upon. In fact, it can be generally stated that graduates from schools with recognized analytical curricula are offered salaries 5–10% higher than comparable students in organic synthesis or engineering. It is the principle of supply and demand coming into play. This can be illustrated from the author's experience in personnel recruitment of various types of chemists at the colleges and universities. My average is 15 "synthesis" organic chemists processed per job opening in synthesis research, while only one analytical chemist was processed per job opening (inorganic and engineering recruitment were outside my assignment). This shows the response per job and the scarcity of personnel trained and/or educated in the field of analytical chemistry. In *Chemical and Engineering News* there are many advertisements which specify *analyst or analytical chemist*, and often even the specialty.

The colleges and universities have responded to this surge of analytical activity by augmenting as well as rearranging their curricula. The biggest change has been to move analytical chemistry to a later position in the undergraduate curriculum. The reasoning is that mastery of analytical chemistry as it exists today, requires a knowledge of physical and organic chemistry as well as more advanced mathematics.

It should be added that the content of these analytical chemistry courses has been changed as well as the position in the education time table. No longer is analytical chemistry a "qual-quant" course, it has proceded well beyond volumetric-gravimetric analysis. The courses now include the broad spectrum of tools and knowledge available to solve analytical problems.

Also the number and variety of analytical courses available to the students have increased. Undergraduate courses in instrumental analysis and organic analysis are almost standard offerings. On the graduate level, the training diversifies broadly with some of the analytical specialty areas being covered in separate courses.

It is hoped that the above statistics will serve to put analytical chemistry in the perspective in which it exists today relative to the other chemical technologies. It is also hoped that the emphasis on analytical chemistry in the schools will continue with more schools revamping and augmenting their curricula to provide a better balance of recruits for the chemical field.

An Enrichment Program in Chemistry for the Advanced High School Student

This program for selected high school students who have completed a year of chemistry was designed to enrich backgrounds in chemistry, to increase interest in the science as a professional field, and to prepare them better for collegiate work. It consists of 8 three-hour lecture-discussion-demonstration sessions and 2 four-hour laboratory sessions (syntheses of aspirin and anthraquinone; determination of the half-life of artificially activated indium), all conducted on Saturdays. The overall theme of the program is "the influence of detailed structure on properties," the exact subject coverage having been chosen on the basis of the principal deficiencies in the average high school and introductory college courses.

After considering classical and modern ideas concerning time, position, velocity, and energy, the basic results of quantum mechanics and orbital theory are introduced to enable a systematic building up of the periodic table. Subsequent discussions of the chemical bond (including resonance theory) and crystal structure are concluded by demonstrations of the use of X-ray diffraction equipment and the electron microscope.

A limited number of simple organic compounds—halides, amines, carboxylic acids, esters, phenols, alcohols, nitro compounds—are considered from the standpoint of functional group reactions previous to considering modern concepts of acids and bases. Simple examples of S_N1 and S_N2 mechanisms and a discussion of elementary protein chemistry complete the introduction to organic chemistry. The final session is devoted to the nature of the nucleus and radiochemistry.

Supplementary reading consists of Gamow's *Mr. Tompkins in Wonderland* (Macmillan, 1940), Ryschkewitsch's *Chemical Bonding and the Geometry of Molecules* (Reinhold, *1963*), and five reprints from *Scientific American*. Anyone interested in further details concerning this highly successful program is invited to write the author.

Modified Victor Meyer Apparatus

The determination of vapor density by the Victor Meyer method has long been a useful determination taught in the physical chemistry laboratory. As usually performed, the experiment is rather cumbersome since it involves making and filling sample bulblets, heating a rather large steam jacketed vessel and measuring a displaced volume of air. A student who had had a course in gas chromatography, casually remarked that the sample should be injected with a syringe. The following apparatus was constructed to use a microsyringe for sample introduction and, incidentally, to reduce the size of the equipment and the time required for a determination.

Description of Apparatus. The apparatus consists of a Pyrex glass tube (*A*) about 40 cm long and 3.5 cm in diameter (see Fig. 1). A slight enlargement (*B*) is

Semi-micro Victor Meyer apparatus.

blown on the lower end to receive the liquid which is refluxed to supply a constant temperature jacket. A 15 cm length of 2 cm tubing (*C*) has lengths of 8 mm tubing sealed to each end. The lower length is bent at a right angle and cut to fit inside the jacket. The upper 8 mm tube is secured in the top of the jacket by a ring seal. The lower one is then sealed through the wall of the jacket and the opening (*D*) is tooled to accept a 6 mm silicone puncture type seal or septum. A side-arm (*E*) to receive a small reflux condenser is provided near the top of the instrument. The portion of the instrument between the septum and the condenser side-arm is insulated with a layer of aluminum foil and a layer of loose asbestos cloth.

The upper, or exit, tube (*F*) of the Victor Meyer apparatus is joined by means of a 0.5 mm bore capillary (*G*) to the gas buret (*H*). Short lengths of rubber tubing are used to make the connections. The gas buret has a capacity of 10 ml and may be made conveniently from a 10 ml graduated pipet. The leveling bulb (*I*) is a length of glass tubing of about the same diameter as the pipet. The confining liquid is mercury.

Operation of the Apparatus. A few milliliters of ethylene glycol are added through the condenser side-arm and heated to rapid reflux. The delivery tube (*G*) is detached from the gas buret (*H*), and an aspirator is attached to draw air through the hot apparatus. The delivery tube is replaced, the mercury is leveled, and a silicone seal is pushed into the opening (*D*). A very small funnel made of glass tubing is inserted in the hole in the seal. This enables one to thrust the needle quickly through the septum even though the area around the septum is quite hot. A small syringe needle may be introduced through the septum so that atmospheric pressure is re-established inside the apparatus.

A microsyringe is filled to the desired volume with sample, the usual precautions being taken to eliminate all air bubbles. The end of the needle is closed by thrusting it into a small piece of a silicone plastic and the syringe is weighed. Next, the empty needle is withdrawn from the septum at *D* and the gas buret is read. Then the silicone plug is removed from the syringe needle, the plunger is withdrawn enough to empty the needle back into the syringe body. The needle is thrust through the septum and the sample injected. The leveling bulb is lowered to the correct level. The plunger of the syringe should be withdrawn again to empty the liquid remaining in the needle back into the syringe. The needle is then plugged again and reweighed; the amount of sample vaporized is found by difference. Sample vapor volume is read from the buret. This detailed procedure for introducing the sample is necessary to be sure that all the sample which leaves the syringe—and only that—is introduced inside the apparatus.

The author acknowledges with pleasure the assistance of Arthur P. Ingram and Harry K. Montgomery, Jr., both of the University of Houston, and Kenneth M. Richards, Brevard Junior College, Cocoa, Florida.

The table illustrates results obtained. In the first series of determinations on methylene chloride two determinations were rejected out of 13, since the deviations were four times the average deviation. The next three determinations are composed of 10 consecutive cases, each with no rejections. The precision of the measurements, indicated in the last column, seems to be as good as the precision of weighing the sample and of measuring the displaced air. A typical sample weighed 0.0413 g as measured on a Type H5 Mettler balance. A typical volume measured 6.43 ml as read in a buret graduated to 0.1 ml.

Summary of Results

Number of cases	Substance	Formula weight	Mol. wt. experimental	Precision
11	CH_2Cl_2	84.94	85.2	85.2 ± 0.5
10	CCl_4	153.84	154.8	154.8 ± 2.9
10	C_6H_6	78.11	78.1	78.1 ± 0.4
10	CCl_4	153.84	153.7	153.7 ± 0.8

In the first two sets of determinations the apparatus was insulated only with aluminum foil. Asbestos insulation was added for the other two sets of determinations.

Static and Kinetic Measurements of an Equilibrium Constant

A physical-inorganic chemistry experiment

Doyle Britton and
Z Z. Hugus, Jr.
University of Minnesota
Minneapolis

The assumption is often made in discussions of the kinetics of reversible reactions that, since at equilibrium the forward reaction rate equals the back reaction rate, the equilibrium constant must be related to the rate constants for the forward and back reactions. To use a common example

if

$$H_2(g) + I_2(g) \xrightarrow{k_f} 2\ HI(g)$$

and

$$2\ HI(g) \xrightarrow{k_b} H_2(g) + I_2(g)$$

then for any way of writing the balanced equation the associated equilibrium constant is related to these rate constants.

For example,

$$H_2(g) + I_2(g) = 2\ HI(g)$$
$$K = [HI]^2/[H_2][I_2] = k_f/k_b$$

or

$$^1/_2\ H_2(g) + {}^1/_2\ I_2(g) = HI(g)$$
$$K' = [HI]/[H_2]^{1/2}[I_2]^{1/2} = (k_f/k_b)^{1/2}, \text{ etc.}$$

We have felt it desirable in our senior-first year graduate inorganic chemistry laboratory course to include an experiment in which the students can test this assumption by measuring the equilibrium constant directly and comparing this to the equilibrium constant deduced from their own measurement of the kinetics of the forward and back reactions.

There are two particular advantages that we recognize in this experiment. First, it demonstrates an important theoretical point to the student; and second, it provides an experiment, more complex than the usual one, that requires the student to bring together several results and intermediate conclusions, each of which could have been a valid study in itself.

We have chosen the reaction that historically provided the first complete experimental demonstration of the relation between kinetics and equilibrium. Roebuck, (*1*, *2*) studied the reaction

$$H_3AsO_4 + 3I^- + 2H^+ = H_3AsO_3 + I_3^- + H_2O \qquad (1)$$

and found that the forward rate law was

$$\frac{d[I_3^-]}{dt} = k_f[H_3AsO_4][I^-][H^+] \qquad (2)$$

and the back reaction kinetics were given by

$$-\frac{d[I_3^-]}{dt} = \frac{k_b[H_3AsO_3][I_3^-]}{[I^-]^2[H^+]} \qquad (3)$$

His numerical results, as recalculated by Liebhafsky (*3*) in modern units, were, at 0°C

$$K = 6.2\ \text{mole}^{-4}\ \text{liter}^4$$
$$k_f = 1.05 \times 10^{-4}\ \text{moles}^{-2}\ \text{liters}^2\ \text{sec}^{-1}$$
$$k_b = 1.57 \times 10^{-5}\ \text{moles}^2\ \text{liter}^{-2}\ \text{sec}^{-1}$$
$$k_f/k_b = 6.7\ \text{mole}^{-4}\ \text{liter}^4$$

which demonstrate the equivalence of K and k_f/k_b within experimental error. Other work (*4–6*) has confirmed and extended these results although there is still some question (*6*) about the mechanism of the reaction.

The equilibrium constant is determined directly by rapid titration, and the forward and back reaction kinetics are determined by following the formation or disappearance of triiodide ion spectrophotometrically.

The system is studied at only one temperature, 25°C, in our laboratory, although this could be extended readily to other temperatures if it were felt worth while to spend the time. In order to keep the experiment within reasonable time limits we have allowed the students to take certain things for granted, pointing out to them that this is not possible in an original piece of work. We anticipate for them that the neutral acids H_3AsO_3 and H_3AsO_4 are the important species, and that the possible anions of these acids do not react at a significant rate. Also, we tell them to assume that the order of the reaction is integral with respect to each species and that the absence of fractional orders or of complex reactions can be assumed.

Preliminary Considerations

The Species in Solution. Both H_3AsO_4 and H_3AsO_3 are weak acids, so the *p*H must be kept low in order to ensure that the concentrations of the neutral acids are essentially equal to their formal concentrations. Since K_1 for H_3AsO_4 is 2.5×10^{-4}, and H_3AsO_3 is weaker still, a *p*H lower than 2 will satisfy this condition.

The triiodide ion dissociates to aqueous iodine and iodide ion: at 25°C, moles/liter

$$k_{diss} = 1.4 \times 10^{-3}$$

In order to be able to consider the reaction in the form written above without correcting for the I_2 concentration the free iodide concentration is kept 0.1 *M* or larger.

Ionic Strength. The activities of the various ionic species depend upon the ionic strength and would change appreciably from experiment to experiment as the concentrations are varied. In order to reduce this complication the ionic strength in all stock solutions is made 1.0 *M* by the addition of sodium perchlorate. The fractional change in ionic strength as a result of the reaction is then small and the activity coefficients of the various species remain constant to a good approximation.

Temperature Dependence. The equilibrium constant and the rate constants are temperature dependent. The activation energies for the reactions are 14.1 kcal/mole for the forward reaction (*5*) and 17.0 kcal/mole for the back reaction (*6*). This means that a one degree change in temperature changes the forward and reverse rate constants by factors of 1.08 and 1.10 respectively, a five degree change, by factors of 1.49 and 1.61. In order to make a meaningful comparison of the measured constants all experiments must be made at the same temperature. If the laboratory temperature is not constant to one degree, a constant temperature bath should be used. It is clear from the activation energies that the equilibrium constant is much less temperature sensitive; the correction factors for one degree and five degree changes are 1.02 and 1.09. If temperature variations cannot be avoided the results in each part should be corrected to 25° before they are compared.

The Experiment

In addition to ordinary laboratory glassware, a spectrophotometer is necessary and a constant temperature bath is desirable.

The following solutions are necessary (each number indicates the number of significant figures to which the concentration should be known and not the exact value): 1.000*M* $HClO_4$; 1.000 *M* NaI; 0.150 *M* NaI_3 plus 0.250 *M* NaI in 0.60 *M* $NaClO_4$; 0.500 *M* H_3AsO_4 in 1.00 *M* $NaClO_4$; 0.200 *M* H_3AsO_3 in 1.00 *M* $NaClO_4$; 0.1000 *M* $Na_2S_2O_3$. Note that, except for the thiosulfate, all solutions have ionic strength 1.0 *M*. In all of the parts that follow, unless it specifically states that a rough measurement is being made, accurately known amounts of the various solutions are used although the actual amounts need not agree exactly with those given below.

The Equilibrium Constant. Four solutions with the compositions shown in Table 1 are made up, and are left to equilibrate overnight. After at least 24 hr 25 or 50 ml aliquots are titrated *rapidly* with thiosulfate to the marked lightening of the iodine color. *No starch is used.* It must be realized that the end point is not stable. This method was chosen over a spectrophotometric measurement or equilibrium with an organic solvent to emphasize to the student that if the measurement time is short compared to the reaction time the system does not need to be truly static. From the equilibrium amount of iodine, assumed to be in the form I_3^-, the concentrations of all species, and thence the equilibrium constant, can be calculated.

Table 1. Molar Concentrations in Solutions Used for Equilibrium Measurements

S-11	0.08	0.1	0.1
S-12	0.08	0.2	0.1

The Kinetics of the Forward Reaction. The order of the forward reaction with respect to the various species is first determined in a qualitative experiment. Eight solutions, of the compositions shown in Table 2, are prepared by adding the previously measured volume of iodide solution from eight beakers to the previously mixed acid, arsenic acid, and diluting water, as nearly simultaneously as possible. Triiodide is formed in all the solutions immediately and after a minute or two they are arranged in order of their intensities and the order recorded. The initial rate is

$$\frac{d[I_3^-]}{dt} = [H_3AsO_4]^x[I^-]^y[H^+]^z$$

and, as can be seen from the concentrations used, the initial rates should all be the same or different by powers of two if x, y and z are integers as the students have been told to assume. An inspection of the order of increasing rates, which is ideally

$$6 < 5 \sim 7 \sim 8 \sim 9 \sim 11 < 10 \sim 12$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

allows the choice $x/y/z = x/x/x$ to be made. Since the students are told to choose the smallest set of integers that satisfy the ratio, 1/1/1 is chosen. For any other ratio of $x/y/z$ a quite different order would obtain, and even though the students do not get all solutions correctly ordered (they usually tend to judge differences too closely) the 1/1/1 ratio gives the most consistent agreement.

In preparation for the spectrophotometric determination of the rate constants the students determine the extinction coefficient of triiodide as a function of wavelength from 400–600 mμ, and choose a wavelength at which the optical density of a 10^{-3} M solution in a 1 cm cell is about 0.5 for use in all the kinetic measurements.

Figure 1. Optical density versus time for the forward reaction (475 mμ). From the slopes the following rate constants were calculated (in moles^{-2} liter^2 sec^{-1}):

S-5 $k_f = 1.59 \times 10^{-3}$
S-6 $k_f = 1.31 \times 10^{-3}$
S-10 $k_f = 1.57 \times 10^{-3}$

Figure 2. Determination of the order of the back reaction with respect to (I_3^-). The optical density, the log of the optical density, and the reciprocal of the optical density are plotted against time. The linearity of the log plot indicates a first order reaction.

When a suitable wavelength has been determined, three of the solution compositions from Table 2 are selected for the accurate kinetic measurements. These solutions are made up accurately this time, with the time of mixing carefully noted, and readings of the optical density are taken every 1–2 minutes until the optical density is between 0.5 and 1.0; usually this requires about 30 minutes. The three solutions plus a blank solution can all be accommodated in the spectrophotometer cell holder (Beckman Model DU or Model B) so that all of these readings can be taken during the same period of time.

The conditions chosen here are such that no appreciable amount of the reactants is used up; thus the right side of equation 2 can be assumed constant. The slope of a plot of (I_3^-) or of the optical density, D, versus time then allows the rate constant to be calculated in a straightforward way. Figure 1 shows a typical set of results for this part of the experiment.

The Kinetics of the Back Reaction. As with the forward reaction both the form of the rate equation and the value of the rate constant are to be determined. The rate is given by

$$-\frac{d[I_3^-]}{dt} = k_b[H_3AsO_3]^s[I_3^-]^t[I^-]^u[H^+]^v$$

where s, t, u, and v are assumed to be integers. In the study of this rate law quantitative measurements are made immediately, but otherwise the approach is similar to the study of the forward reaction. The triiodide concentration is followed spectrophotometrically as a function of time in six solutions of the compositions shown in Table 3. The reactions are followed for about 20 min by which time at least half of the original triiodide concentration has been used up. Of the species whose concentrations appear in the rate law only the concentration of triiodide ion changes appreciably during the course of the reaction. Therefore, the dependence of rate on (I_3^-), i.e., the exponent t, can be determined directly from a change of (I_3^-) with time. One run is chosen to determine the value of t and plots of D, log D, and $1/D$ versus t are drawn. (The triiodide concentration could be used rather than the optical density, but this involves a considerable amount of unnecessary conversion.) Typical plots of results are shown in Figure 2.

When the correct dependence of (I_3^-) has been decided upon the student plots all six runs on the appropriate plot, and by an inspection of the slopes decides upon the values of s, u, and v. A typical set of curves is shown in Figure 3. From the slopes and the values of the initial concentrations a value of k_b can be calculated for each of the six solutions.

Figure 3. Log optical density versus time for the back reaction (475 mμ). From the slopes the following rate constants were calculated (mole^2 liter^{-2} sec^{-1}):

S-13 $k_b = 7.38 \times 10^{-5}$
S-14 $k_b = 7.08 \times 10^{-5}$
S-15 $k_b = 6.66 \times 10^{-5}$
S-16 $k_b = 6.54 \times 10^{-5}$
S-17 $k_b = 6.81 \times 10^{-5}$
S-18 $k_b = 7.23 \times 10^{-5}$

(The acid concentration in S-16 was four times that given in Table 3.)

Results and Discussions

At this point the student has determined four values of the equilibrium constant, three values of the forward rate constant, and six values of the back rate constant. He is therefore in a position to calculate a mean value for each constant, and to estimate the error of his measurement. At the option of the instructor a careful error analysis can be made, or the average deviations of a given student's results can be used as a measure of their accuracy.

In Table 4 are shown some results from our most recent group of undergraduates. Eight pairs of students did the experiment. The results of the best pair (best as judged from internal consistency and from other evidence of careful work) and the worst pair and the average results of the entire class, are shown. The averages were weighted according to the average deviations of the individual data, so that, for example, a value of 25.0 ± 2.0 was given four times the weight of a value 22.0 ± 4.0. All error estimates are average deviations, or are derived from average deviations by the usual formula for propagation of error (*7*).

There are no literature values at ionic strength 1.0 to compare with our results, but Washburn and Strachan (*8*) have made a careful study of the equilibrium constant at 25° and low ionic strength, and Wilson and Dickinson (*5*) have measured k_f at 25° from the exchange of radioactive arsenic between arsenious acid and arsenic acid in the presence of iodide. These values as well as the calculated value of k_b are shown for comparison. The differences between our values and the literature values are surprisingly small and might appear to be in the wrong direction to be accounted for by the difference in ionic strengths. However, consideration of equation (1) shows that hydrogen iodide provides a reasonable model compound for ionic strength effects in this system, and the mean activity coefficient for hydrogen iodide solutions is nearly 1 at ionic strength 1.0 (*9*).

Acknowledgments

We should like to thank the teaching assistants who have assisted in this course over the last several years for their comments and criticisms. We are indebted to Professor Robert Livingston for a helpful discussion of ionic strength effects.

A dynamic method for Measuring Dissociation Pressures

Measurements of dissociation pressures have long been of interest, both from the fundamental and practical viewpoint. Although each material under study requires some special consideration, a host of materials dissociate into products where one of them is in the gaseous state, e.g.,

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$$

For such systems various techniques have been employed with the most widely used corresponding to a static vapor pressure measurement. This communication reports a simple and rapid method based on the thermogravimetric principle in a controlled atmosphere yielding equilibrium dissociation pressures.

Figure 1. Thermogravimetric system for dissociation pressure measurements: *A*, balance with optical scale; *B*, furnace; *C*, sample crucible; *D*, furnace tube; *E*, flow-meters; *F*, thermocouple to recorder; *P.G.*, product gas; and *I.G.*, inert gas.

The essential equipment consists of a furnace, a balance, preferably a single pan type with an optical scale, flow-meters and a temperature monitoring device. The system arrangement is shown in Figure 1. For evaluation of the technique $CaCO_3$ was used. In brief, the following procedure was adopted. A crucible containing reagent grade $CaCO_3$ was freely suspended inside a furnace tube from a precision analytical balance featuring an optical scale (100 mg range). The tube presenting a closed system had a bottom gas inlet and a small hole on top serving for the free passage of the suspension wire and as gas outlet. A thermocouple was positioned as near as possible to the suspended sample without making actual contact. A desired partial pressure of CO_2 was established in the tube by monitoring the flow rates of predried N_2 and CO_2. The total pressure of the gas stream at all times was equal to atmospheric pressure. With the CO_2 pressure fixed, the furnace was heated and temperature and weight changes were monitored. When the sample temperature exceeded the equilibrium temperature for the fixed CO_2 pressure, the sample weight decreased corresponding to a loss of CO_2 and the formation of CaO. The temperature was then decreased until the reverse reaction took place and the sample weight began to increase. By cycling the temperature several times through the temperature at which no weight change occurred, it was possible to determine the true equilibrium temperature within 1°C for the particular fixed CO_2 pressure. Since the gas flow rates are readily adjustable, the equilibrium pressures can be measured up to one atmosphere. The results on $CaCO_3$ indicate a dissociation pressure of one atmosphere at 899°C which is well within the limits of 895 to 902°C reported more recently in the literature.[2,3] Results are shown in Figure 2 for measurements on $CaCO_3$, Li_2CO_3, and Na_2CO_3. For the latter two, where the systems are molten, the rates of weight gain or loss are less than for $CaCO_3$, undoubtedly because of the greatly decreased surface areas presented by the melts.

Figure 2. Dissociation pressures: —○—○—, $CaCO_3$–CaO; —△—△—△—, Li_2CO_3 (mp 710°C)-Li_2O; —□—□—, Na_2CO_3 (mp 858°C)-Na_2O.

The present method has several advantages over other techniques, some of which warrent mention. The dynamic method is simple and rapid and requires equipment which is standard in most laboratories. Equilibrium pressures of the product gas are measured truly. The results are independent of the presence of any small impurity phase which on heating may also yield a gaseous product, e.g., H_2O vapor. The technique has been used successfully for solids and liquids in this laboratory. The method is especially useful in cases where at times weeks are required before total equilibrium is reached. For instance, in the static dissociation pressure measurement of $CaCO_3$ it took three weeks to reach equilibrium at 450°C and several hours at 800°C.[2] By nature of the dynamic method the same results are attained in the order of an hour or less depending mainly on the maintenance of thermal equilibrium in the temperature cycling.

William Allen Miller: Pioneer Stellar Spectroscopist

The practice of naming lunar formations after celebrated scientists, philosophers, and theologians was first instituted in 1651 by the Jesuit astronomer Riccioli. The system has not only survived until the present day but has grown so that there are several hundred formations thus identified. Included in the list of the honored are eleven chemists: Berzelius, Boussingault, Cavendish, Davy, Klaproth, Lavoisier, Liebig, Miller, Regnault, Wöhler, and Wollaston. The names of most of these men are familiar and their achievements are recorded in the standard works on chemical history. William Allen Miller, an eminent scientist in his own day seems, however, to have slipped into obscurity in ours.

Miller was born December 17, 1817, at Ipswich, in Suffolk County, England. His taste for the sciences was acquired during his two years at Ackworth, a school belonging to the Society of Friends, in Yorkshire. Here, in addition to attending occasional lectures and demonstrations in chemistry, Miller was sometimes invited to view the heavens through a telescope belonging to one of the masters.

At the age of 15, Miller was apprenticed to his uncle, Bowyer Vaux, a surgeon in the General Hospital at Birmingham. It was this hospital in which Miller's father served as secretary for nearly 20 years. At the end of a five-year apprenticeship Miller became a medical student in King's College in London. Here his knowledge of chemistry quickly attracted the attention of Professor J. F. Daniell; and when the laboratory assistant was taken ill, Daniell used Miller as his substitute. In 1839 Miller won the Warneford prize for the encouragement of theological studies among medical students.

In 1840 Miller visited Germany and spent a few months in Liebig's laboratory at Giessen. Upon his return to London he was appointed to the post of demonstrator in the laboratory of King's College. In 1841 he was appointed assistant lecturer to Professor Daniell, and also took the degree MB in the University of London, the MD degree being attained the following year. Miller assisted Daniell in research problems, and in 1844 they appeared as co-authors of a paper entitled "Additional Research on the Electrolysis of Secondary Compounds" (*1*), an outgrowth from Daniell's earlier work in electrolysis.

William Allen Miller

In 1845 Miller was elected a Fellow of the Royal Society. The same year saw him appointed to the chair of chemistry in King's College, vacant because of the sudden death of Daniell.

In this capacity Miller continued studies in the field of spectroscopy. The first of what was to be a long series of papers in this area was presented to a meeting of the British Association for the Advancement of Science at Cambridge in 1845, and published in the

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Philosophical Magazine (*6*). Continuing a line of work begun by Sir David Brewster and extended by Daniell, Miller attempted to unravel the mysteries of the Fraunhofer lines in the solar spectrum.

In addition to the series of papers on spectral studies, Miller took a strong interest in the examination of water and in 1865 published a series of proposed standard methods to bring order out of chaos in this field (*5*). His work was not, however, confined to these two fields. No less than 21 papers bearing his name and dealing with a wide variety of subjects attest to the diversity of his interests.

An active member of the Bristish Association for the Advancement of Science, he served two terms as secretary of its Chemistry and Mineralogy section, five terms as its vice-president, and three as president. With the exception of 1852 he was a member of the Council of the Association from 1851 to 1869. He also served on a number of its committees investigating scientific problems.

Stellar Spectroscopy

Miller's most significant work, and that for which he received the greatest honor, began in January of 1862 following the delivery of a lecture on spectrum analysis to the Pharmaceutical Society of London. The meeting had been attended by the astronomer William Huggins, Miller's friend and neighbor; and on the homeward journey Huggins suggested a plan to use his telescope in conjunction with Miller's spectroscope to study the spectra of the celestial bodies. This fortunate union was to bring forth several "firsts" for the two scientists. In 1864 papers were presented to the Royal Society (*2, 3*) and the Brisish Association for the Advancement of Science (*7*) reporting the first attempt to determine the elements present in stars by spectral analysis. The spectroscope had been so constructed that a reference spectrum of the element being sought could be placed in juxtaposition with the stellar spectrum. In this manner the presence of the element could be proved by the exact coincidence of the lines of two the spectra rather than by an approximation of positions required by other methods. During the course of the investigation the spectra of some 20 of the brighter stars in the sky were studied, and the frequency of the appearance of the lighter elements was noted.

On the basis of these observations they concluded that,

> The differences which exist between stars are of the lower order, of differences of particular adaptation, or special modification, and not differences of the higher order of distinct plan of structure. There is therefore a probability that these stars, which are analogous to our sun in structure, fulfil an analogous purpose, and are, like our sun, surrounded by planets, which they by their attraction uphold, and by their radiation illuminate and energize. . . . It is remarkable that the elements most widely diffused through the host of stars are some of those most closely connected with the constitution of the living organisms of our globe, including hydrogen, sodium, magnesium, and iron. . . . On the whole we believe that the foregoing spectrum observations on the stars contribute something toward an experimental basis on which a conclusion, hitherto but a pure speculation, may rest, viz., that at least the brighter stars are, like our sun, upholding and energizing centres of systems of worlds adapted to be the abodes of living beings.

Studies were also made of the spectra of the moon and the planets, and evidence was presented that the atmospheres of Saturn, Jupiter, and Mars were quite different from that of the earth, while the moon was found to be without an appreciable atmosphere.

In May of 1866 the star now known at T *Coronae Borealis* rose, in a matter of a few hours, from an invisible magnitude of 9.5 to a bright magnitude 2, and then slowly faded back to obscurity. Four nights after the outburst the star was still at third magnitude, and the spectrum was examined by Miller and Huggins and reported to the Royal Society the following day.

> When the spectroscope was placed on the telescope, the light of this new star formed a spectrum unlike that of any celestial body which we have hitherto examined. The light of the star is compound, and has emanated from two different sources. Each light forms its own spectrum. In the instrument these spectra appear superimposed. The principal spectrum is analogous to that of the sun, and is evidently formed by the light of an incandescent solid or liquid photosphere, which has suffered absorption by the vapours of an envelope cooler than itself. The second spectrum consists of a few bright lines, which indicates that the light by which it is formed was emitted by matter in the state of a luminous gas. . . . The character of the spectrum of this star, taken together with its sudden outburst in brilliancy and its rapid decline in brightness, suggests to us the rather bold speculation that, in consequence of some vast convulsion taking place in this object, large quantities of gas have been evolved from it, that the hydrogen present is burning by combination with some other element and furnishes the light represented by the bright lines, also that the flaming gas has heated to vivid incandescence the solid matter of the photosphere. As the hydrogen becomes exhausted, all the phenomena diminish in intensity, and the star rapidly wanes (*4*).

For their studies in this field the Royal Astronomical Society presented its Gold Medal to Huggins and Miller in 1867. It was necessary upon this occasion to suspend the bylaws of the Society to permit the award of the Medal to Miller, as he was not a member of the Society (*8*). Huggins had received the Gold Medal of the Royal Society in 1866, but Miller's position as vice-president and treasurer of the Society, and his consequent membership on its Council, forbade any consideration of his participation in the award (*9*).

Miller was one of the founding members of The Chemical Society, serving as a vice-president for five years, and president in 1855–6 and 1865–6, as well as a member of its Council from its founding until 1870. Many honors come to him, including honorary LLD degrees from the Universities of Edinburgh and Cambridge, an honorary DCL from Oxford, and an appointment as Assayer of the Mint and of the Bank of England. Following a brief illness, Miller died in September of 1870 at the age of 53.

Chem Ed

BOOK REVIEWS

Elementary Quantitative Analysis

W. J. Blaedel and *V. W. Meloche*, both of the University of Wisconsin, Madison. 2nd ed. Harper and Row, Publishers, New York, 1963. xi + 964 pp. Figs. and tables. 16.5 × 23.5 cm. $9.60

An excellent text has been improved in this Second Edition, although the review of the First Edition (J. CHEM. EDUC., **34**, A283 [1957]) could be repeated almost verbatim. The most important change is the addition of an extensive chapter on Complexation Titrations. The authors are to be commended on their development of complex equilibria and their graphic presentation of the advantages of chelons in analytical chemistry.

Other major changes include: addition of an experiment on potentiometric determination of chloride, addition of a large number of questions and problems to an already impressive collection, exclusive use of the Brønsted treatment in acid-base equilibria (formerly in Supplement), and expansion and updating of the literature references.

Minor changes include: use of larger type for headings, removal of asterisks from more difficult problems (confusion remains with two or more problems on the same page with the same number), numerical changes in the data in many problems, revision of material on growth of crystals and purity of precipitates, balancing of redox equations with half reactions (formerly in Supplement), addition of material on mechanism of redox reactions to the Supplement, omission of the quinhydrone electrode, emphasis on spectrophotometry instead of simple colorimetry, etc.

In spite of these obvious improvements, this reviewer feels more critical of this edition than the first. It is now six years later, and we are still assumed to be teaching essentially the same material as 20 years ago. In other divisions of chemistry, radically new approaches have appeared which reflect the advance of chemistry. While this book is at the top of the list of traditional texts, it fails to give an adequate presentation of current analytical chemistry. For example, the table on page 13, "A Survey of Analytical Publications on Various Methods of Measurements," is out of date. Yet the balance of emphasis in this text is even farther behind the times. With over 900 pages at their disposal and a wealth of other texts to improve upon, the authors might have produced a masterpiece—and they have! But in 1963, why are visible spectrophotometry, potentiometry, and complexation titrations still relegated to "Special Topics"? Where are ion exchange, solvent extraction, various kinds of chromatography, ultraviolet and infrared spectrophotometry, electrochemical methods, radio-counting techniques? The argument for their omission given by the authors in Chapter 22 is not convincing. On page 540, methods based on thermal properties (e.g., DTA and GC detectors) are dismissed with the notation, "not frequently used, but frequently valuable"—the same statement made in the first edition. At this level one does not expect an exhaustive treatment, but there must be some overview of all analytical techniques and the kinds of information they can supply other than straight forward analysis of samples. This is especially true as the time devoted to analytical chemistry must diminish and most students will not take another analytical course.

The above remarks apply to most of the recent texts on elementary analysis. This is a superb source of information for the limited area it is intended to cover, and will be welcomed by all teachers who are giving a traditional course at the sophomore level.

ROBERT L. PECSOK
University of California
Los Angeles

Fundamentals of Analytical Chemistry

Douglas A. Skoog, Stanford University, Stanford, California, and *Donald M. West*, San Jose State College, San Jose, California. Holt, Rinehart, and Winston, New York, 1963. xii + 786 pp. Figs. and tables. 15.5 × 23.5 cm. $8.50.

This text is aimed primarily at sophomore-level chemistry students, and stresses "an appreciation for the over-all analytical process." The book consists of two major portions. The first includes topics generally considered as classical analytical methods, containing sections entitled Introduction, Gravimetric Analysis, and Volumetric Analysis, and accounts for about two-thirds of the book. The remaining portion of the book treats electrical and optical methods of analysis, and several miscellaneous topics, including sampling, attack of samples, and separations. Although the preface states the authors aim to emphasize similarities between classical and instrumental methods, there is very little connection between these two main sections of the book.

In general, the book stresses practical techniques and analytical calculations rather than fundamental chemical principles. The approach has been to compile a large number of determinations and reactions, but to discuss few in any detail. For example the book contains a most comprehensive listing of determinations based on oxidation-reduction titrations, including those based upon titrants such as bromate, periodate and chromous ions. On the other hand, the induced reaction of chloride ion and permanganate during the well-known titration of iron is only mentioned, induced reactions are not defined, and the mechanism of the reaction and the function of the Zimmermann-Reinhardt solution are not discussed. Titrations based on complex-formation reactions are described, including the use of EDTA as a titrant, but only two pages are devoted to a discussion of what a complex ion is, how it is formed, chelate compounds, instability constants,

etc. The discussion of equilibria calculations and especially acid-base titration curves is very good, although the use of Arrhenius (hydrolysis) rather than Brønsted concepts in the calculations is disappointing.

The second portion of the book is intended for a second semester course, but really only covers a portion of what is modern instrumental analysis. This reviewer, an electroanalytical chemist, questions the prevailing practice of writers of elementary quantitative analysis texts of devoting a large portion of their books to the relatively complex subject of electroanalytical chemistry, to the almost complete exclusion of many easily understood and widely used techniques. For example this text devotes 126 pages to electroanalytical methods, but only two pages to gas chromatography. Some of the more esoteric topics, such as differential potentiometric titrations and kinetic and catalytic currents in polarography, might have been left to monographs. Similarly discussions of overpotential and diffusion presented to students before they have had physical chemistry, seems unwise.

The book contains about 400 problems and numerous references to the literature, including a good brief description of the literature of analytical chemistry. In general the book is carefully and clearly written with few errors of fact. One misstatement repeated several times concerns the standard potential of the standard hydrogen electrode, which is defined as zero at all temperatures, not only at 25°. The figures are good, and the price seems reasonable. The book certainly deserves consideration as a text for a course stressing practical analytical chemistry and a detailed survey of analytical methods.

Analytical Chemistry, 1962: The Proceedings of the International Symposium held at Birmingham University, April, 1962.

Edited by *Philip W. West*, Louisiana State University, Baton Rouge, and *A. M. G. MacDonald* and *T. S. West*, University of Birmingham, England. American Elsevier Publishing Co., New York, 1963. x + 411 pp. Figs. and tables. 17 × 24.5 cm. $16.

The 1962 International Symposium on Analytical Chemistry was held in honor of Fritz Feigl to commemorate his 70th birthday. For this reason, a considerable portion of the meeting was devoted to spot test and the role of organic reagents in analytical chemistry. The papers in this area vary in scope and treat such general topics as oxidation potentials in qualitative analysis or specific subjects such as Vic-Dioximes as analytical reagents. Some papers dealing with spot analysis seem to be designed to discuss the present status of a general area such as the detection of pharmaceutical products by spot test reactions.

There are sections of this work which deal with subjects such as electrochemical, radiochemical, and optical methods of analysis. Topics of current interest such as atomic absorption spectroscopy, differential electrolytic potentiometry, and cathode ray polarography are treated by outstanding research workers in these fields.

There are small sections dealing with separation processes and titrimetric analysis and miscellaneous topics.

Although the papers, of necessity, are short coupled with the printed discussion of the paper, they are quite worthwhile. This book will be most useful as a library reference for persons attempting to catch up on the recent developments during the past two years in the areas mentioned.

College of Wooster
Wooster, Ohio

Quantum Theory of Molecules and Solids. Volume 1, Electronic Structure of Molecules

John C. Slater, MIT. McGraw-Hill Book Co., Inc., New York, 1963. Figs. and tables. xv + 485 pp. 16.5 × 23.5 cm. $12.50.

This book represents a further installment of Professor Slater's magnum opus, a general account of the quantum theory of atoms, molecules, and solids. Having treated atomic structure in a two-volume work which appeared in 1960, he has now embarked on an account of the quantum theory of molecules. This volume, the first of the new series, deals with the methods currently available for treating molecular structure, and with their application to some specific problems.

The general construction of the book follows a conventional pattern. The first four chapters deal with the hydrogen molecule and molecule ion, the fifth describes the MO method including the Roothaan SCF treatment, the next two chapters discuss homonuclear and heteronuclear diatomic molecules, chapter eight deals with group theory and symmetry properties of wave functions, chapter nine with Bloch's method for constructing symmetry orbitals together with an introduction to the theory of solids, and the last three chapters deal with ammonia, methane, water, ethylene, and benzene.

The appearance of any book by Professor Slater is always a notable event; there is really no need for the reviewer to say more about this one than that it is well up to his highest standards. It is concise, clear, stimulating, and (as one would expect) full of original ideas and observations; it is also a joy to read. Much of this clarity comes from its construction; the main text occupies little more than half the book, being followed by 146 pages of appendices dealing with mathematical details, ranging from the Virial Theorem and Group Theory to the calculation of molecular integrals. As a bonus there is an extremely comprehensive 80-page bibliography which alone would be worth the price of the whole book—which in any case is most reasonable.

This book is a "must" for anyone with any interest in quantum chemistry. One can only hope that the following volumes will appear in quick succession and that they will be equally good—they could hardly be better.

Michael J. S. Dewar
University of Chicago
Chicago, Illinois

Nuclear Physics and the Fundamental Particles

Harry H. Heckman, Lawrence Radiation Laboratory, University of California, Berkeley, and *Paul W. Starring*, Lodi High School, Lodi, California. Holt, Rinehart, and Winston, Inc., New York, 1963. vi + 410 pp. Figs. and tables. 15.5 × 23.5 cm. Paperbound. $0000.

This paper-back volume for "capable high school students" was written at the request of a group of teachers who had participated in the summer lecture-research program at the Lawrence Radiation Laboratory of the University of California. Many of these teachers felt there was a great need for a text written for high school students which would "both recast and elaborate on the subject of the physics of the nucleus and the fundamental particles." Physicist Heckman of the Lawrence Radiation Laboratory and high school teacher Starring have teamed up to collect in a single volume, a body of information which has hitherto been available largely in college texts on nuclear physics or in the periodical and research literature.

In the opinion of the reviewer the *average* high school student will find this volume difficult. On the other hand the capable student with a good grasp of mathematics will breeze through it and wish that the authors had filled in the gaps in spots where they have indicated, "Using the calculus it is possible to show that . . . ."

The treatment is then, essentially nonmathematical, meaning that only algebraic arguments are used. There is an obvious temptation on the part of the authors to lapse into a bit of calculus here and there, but on the whole they have shown remarkable restraint.

The early chapters deal with atomic structure, basic properties of nuclei and nuclear models, followed by radioactive nuclei, interactions of radiation with matter, particle accelerators and detection of radiation. The next few chapters deal with unstable particles (neutrons, pions, and muons), with strange particles (K mesons and hyperons) and with antiparticles. Finally there are chapters on space physics (cosmic rays and the Van Allen belts) and health physics.

Each chapter has a set of review questions, as well as work problems and calculations. Answers are given to alternate problems. The Appendix includes a glossary of units, symbols and abbreviations, a table of physical constants and conversion factors, and a table of fundamental particles. A table of isotopic masses is not included.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

The authors have preferred a tight, terse style. While this permits more efficient coverage of the field, some chapters tend to be encyclopedic and dry (e.g., Unstable Particles, Antiparticles). Elsewhere in the volume use of historic anecdote has provided some of the "spice" which is so often needed to keep a strictly factual diet palatable.

All in all the work is commendable and should provide the keen high school student and many a high school teacher an excellent summary of the nuclear field.

DONALD S. ALLEN
State University of New York
Albany

Basic Chemistry Problems for High School

John W. Sulcoski, Dallas Senior High School, Dallas, Pennsylvania, and *Stephen Rituper*, Liberty High School, Bethlehem, Pennsylvania. Burgess Publishing Co., Minneapolis, Minnesota, 1963. v + 216 pp. Figs. and tables. 15 × 23 cm. Paperbound. $2.75.

The attempt of the authors to construct a problem book of basic problems for the high school has in part been fulfilled. The authors recognized a basic need for mathematical treatment of scientific information that is lacking in many high school texts currently available. This statement is not meant as a criticism of the available high school texts; it merely points out that the field of education in chemistry has grown so rapidly recently that it is necessary to do as Sulkoski and Rituper have done. They have introduced the mathematics of chemistry for the high school in a separate volume.

The chapter headings show the areas included. The sub-headings allow a student to find at a glance the place in the book he needs. Each topic is discussed in enough depth for the "average" high school curriculum. The text should serve chemistry classes with review problems that the student should do on his own or have assigned.

In light of the newer trends of chemical curricula through programs such as CHEM and CBA the book has its limitations in that it will become dated. It does not show a good development of the mole concept through gases or electrochemistry. Oxidation-reduction is not developed by the E° values. The writer also feels that the treatment of chemical kinetics could have been somewhat more extensive.

"Basic Chemistry Problems for the High School" can serve the teacher of chemistry in a basic course. The use of dimensions or units for problem solving is an excellent method to give to beginning chemistry students. Adequate treatment has been given to problems involving standard solutions. The use of problems and equations concerning nuclear chemistry gives to the teacher examples he might use should his own knowledge be limited. The reviewer recommends this volume to teachers and students of basic chemistry at the high school level to serve them as they need.

Haverford Township Senior High School
Havertown, Pennsylvania

Advances in Chemical Physics. Volumes 4 and 5

Edited by *I. Prigogine*, University of Brussels, Brussels, Belgium. Interscience Publishers (a division of John Wiley and Sons, Inc.), New York, 1962 and 1963. 400 and 410 pp. 15 × 23 cm. $16.50 each.

Teachers of freshman and undergraduate physical chemistry will find the articles in Volume 4 of this series on the theory of optical activity of small molecules (A. Moscowitz), effects of high pressure on electronic structure of solids (H. G. Drickamer and J. C. Zahner), and the structure and properties of metal-ammonia solutions (T. P. Das) particularly interesting sources of new lecture material. Moscowitz breathes new life into the one electron theory of optical rotation of Condon, Altar and Eyring in addition to presenting a very readable, concise survey of the many contributions made in this field since the late 1920's. The article by Drickamer and Zahner illustrates how spectroscopic data on sample systems such as nickel dimethylglyoxime subjected to pressures of the order of 100 kilobars can be used to classify spectra and reveal the interactions between neighboring atoms and ions in crystals. There is almost too much experimental detail in the article by Das to hold the reader's interest, but his synthesis of conflicting theories of metal-ammonia solutions into a new theory that accounts at least qualitatively for the varied experimental results is intriguing. The remaining articles on random walk (F. H. Ree, T. S. Ree, T. Ree, and H. Eyring), optical activity of polymers (I.T inoco, Jr.), the one-dimensional plasma (S. Prager) and the quantum mechanical distribution function of molecular systems: translational and rotational motions (H. Friedmann) are no less authoritative but probably too specialized to interest most chemists. The contributing authors to both volumes generally fulfill Prigogine's promise of presenting well informed points of view rather than encyclopedic literature surveys.

There are eight articles in Volume 5: the one-electron theory of π-electron systems—particularly the aromatic hydrocarbons (H. Hartmann), a ligand field theory treatment of the spectra of the transition metal complexes, the lanthanides and actinides that is much the longest article in the book (C. K. Jørgensen), a treatment of non-spherical molecules both as real gases and in the crystalline state (T. Kihara), theories on the magnetic properties of the compounds of the 3d group metals (S. Koide and T. Oguchi), a succinct exposition of forbidden electronic transitions (A. D. Liehr), a statistical theory of transport processes (J. A. McLennan, Jr.), a quantum mechanical interpretation of nuclear quadropole coupling data (E. Scrocco), and a bimolecular collision theory of chemical reaction rates in dilute gases (B. Widom). The theoretical slant of all these articles will make them less useful to a teacher of undergraduates than the three articles cited above in Volume 4.

Unlike some other review series, there is no apparent editorial drift from the general to the particular in the contents of the five volumes of "Advances in Chemical Physics." Furthermore, the quality of the contributions is unimpeachable; the ready availability of these volumes in university libraries is clearly desirable. However, one minor objection should be raised. A number of subjects, particularly experimental ones such as high resolution nuclear magnetic resonance, mass spectra and Raman spectra, that frequently grace the pages of the *Journal of Chemical Physics* have been displaced from the pages of "Advances" by too frequent articles on statistical mechanics. A balance in subject matter for "Advances" that more accurately reflects the broad interests of chemical physicists would be welcome.

University of Utah
Salt Lake City

Infrared Absorption Spectroscopy

Koji Nakanishi, Tokyo Kyoiku University. Holden-Day, Inc., San Francisco, 1962. ix + 233 pp. Figs. and tables. 19 × 26 cm. $8.

One of the best justifications for writing a new book is that it fills a definite need. The book, "Infrared Absorption Spectroscopy," by Koji Nakanishi employs the approach of learning by doing in order to familiarize the beginning worker in this field with the techniques. The introductory material gives the frequencies at which different groups absorb. This is similar to the information contained in Bellamy's Book. A very useful chapter deals with the shifts and absorption bands. Such factors as concentration and solvent effects are discussed with the aid of diagrams.

The latter part of the book consists of 85 problems in infrared spectroscopy. A student who conscientiously works through these problems should have a clear idea of important factors in the field. The answers are given in a separate section with detailed discussions supporting the deduction.

It would seem feasible to employ this technique in other areas of chemistry to the advantage of the student. This book should prove useful to the senior undergraduate or first-year graduate student who is interested in obtaining a practical knowledge of infrared spectroscopy.

NEW AP BOOKS

Introduction to Modern Biochemistry

By P. Karlson
Translated from the German by Charles H. Doering
1963, 434 pp., $10.00

This important textbook provides a completely integrated guide to the established facts, dominant theories, and modern applications of biochemical research. The work synthesizes the vast knowledge gained in recent years in such fields of research as molecular biology, the chemistry of vitamins and hormones, the constitution and mechanism of action of enzymes, metabolism, and the production, conversion and utilization of energy, and relates this knowledge to biological function.

Interfacial Phenomena

Second Edition

By J. T. Davies and E. K. Rideal
October 1963, 493 pp., $15.00

Review of the First Edition:

"The principles of classical surface chemistry are well and concisely set forth, but the real value of the book is in its comprehensive treatment of modern work . . . . The authors are to be congratulated on a first-class book. Few, if any, others could have presented the modern work as fully or skillfully."—*Nature*

The Biosynthesis of Vitamins

and Related Compounds

By T. W. Goodwin
November 1963, 366 pp., $11.00

This monograph correlates for the first time the information currently available on the biosynthesis of vitamins, surveying in detail the important advances which have been made in the last decade and assessing their significance.

The Chemistry and Function of Proteins

Second Edition

By Felix Haurowitz
1963, 455 pp., $10.00

Reviews of the First Edition:

"There is no rival to this book at present and it is fully worthy of the many readers of which it seems to be assured."—*Science Progress*

"The book is to be recommended as an advanced textbook on the subject as well as a handy reference for workers in the field."—*Journal of the American Medical Association*

Non-Stoichiometric Compounds

Edited by L. Mandelcorn
Fall 1963, about 650 pp., approx. $22.50

This book deals in detail with non-stoichiometric compounds which include oxides, sulfides, selenides, etc., and inclusion compounds of inorganic, organic, and solution types. Particular emphasis is placed on the structural features and physical properties of these systems.

The Proteins

Composition, Structure, and Function

Second Edition

Edited by Hans Neurath
Volume 1, Fall 1963, about 675 pp., $20.00

Review of the first edition:

"Considered together, these four volumes will be referred to for many years, not only for all phases of the chemistry of these important macromolecules, but also for their biological properties and biological activities."
—*Journal of Chemical Education*

SERIAL PUBLICATIONS

Advances in Organometallic Chemistry

Edited by F. G. A. Stone and Robert West
Volume 1, Early 1964 about 300 pp.

This series will publish authoritative reviews on recent developments in all aspects of the chemistry of metal-carbon compounds: structural, theoretical, synthetic, and technological. The first volume will include articles on organosilicon polymers, metal acetylene derivatives, diene complexes, and on nuclear magnetic resonance and vibrational spectroscopy of organometallic compounds.

Survey of Progress in Chemistry

Edited by Arthur F. Scott
Volume 1, October, 341 pp., $7.95

The topics covered in the first volume of the series are: new research tools of the chemist, high temperature reactions, new inorganic structures and their implications for valence theory, metallocene chemistry, oxidation-reduction mechanisms in organic chemistry, the chemistry of biological energy transfer, and the structure of the Grignard reagent.

Progress in Nucleic Acid Research

An International Series
Edited by J. N. Davidson and Waldo E. Cohn
Volume 1, 1963, 424 pp., $13.00
Volume 2, December 1963, about 350 pp., approx. $12.50

This serial publication, which reflects the rapid day-to-day progress in the field of nucleic acid research, presents much more than the standard "Review" of recent literature. It provides a medium for the presentation of new theories and techniques, discussions of controversial material, and publication of timely and significant advances in the field.

Progress in Chemical Toxicology

Edited by Abraham Stolmon
Volume 1, October 1963, about 400 pp., $14.00

This new serial publication will report on the usefulness of the newly developed techniques and methods, and evaluate their toxicological significance. Volume 1 emphasizes methodology related to the development and techniques applicable to the fields of forensic and clinical toxicology.

BOOK REVIEWS

Developments in Inorganic Polymer Chemistry

Edited by *M. F. Lappert* and *G. J. Leigh*, both of the University of Manchester, England. American Elsevier Publishing Co., New York, 1962. xi + 305 pp. Figs. and tables. 14.5 × 22 cm. $10.

Combinations of multivalent elements other than carbon have been studied with unusual intensity during the past ten years, perhaps chiefly because of the need for polymeric materials capable of withstanding temperatures well beyond the useful range of the readily available organic plastics and elastomers. However, most of the promising inorganic chains proved to be too labile or reactive for practical use, and indeed many polymer chains are less stable than small rings made of the same polymer-units. Accordingly, there has been much attention to small-ring compounds, partly because their chemistry was within reach of the usual chemical techniques, but also because the small-ring chemistry had to be well understood before one could hope to stabilize the high-polymer forms.

The present book summarizes a considerable number of these recent developments, without attempting the altogether too large task of covering all types of inorganic polymers in full detail. As a collection of chapters by different specialists, it cannot be expected to maintain uniform quality, and indeed the various authors range from fairly perfunctory to very thorough and scholarly.

In the first chapter, Professor Emeléus very concisely introduces a wide range of types concerning almost exclusively the main-group elements (including some unusual fluorocarbon types); and thereby the novice would gain insight into the kinds of combination which lead to the polymeric condition. Then we find a 33-page chapter by Lappert, reviewing boron-nitrogen polymers and presenting a 5-page bibliography of these interesting near-imitators (with sharp differences) of carbon-chain polymers. The next chapter, by J. M. C. Thompson, extends the analogy farther afield, with mention of boron-hydride polymers, B-B linked oxides, boroxines, copolymers of boron oxide with silicones and other units, boron phosphate types, phosphinoborines, and the very labile sulfur-boron polymers. Then we find a relatively brief but extremely useful survey of the P-N system by an important innovator in that field, N. L. Paddock. Another important contributor, M. Becke-Goehring, tells of her own work in this field, in a chapter covering also her strong interest in the relatively unstable sulfur-nitrogen system.

The famous and almost classical silicone polymer system is modernized in a 22-page chapter by J. S. Hughes, and then J. Idris Jones presents 90 pages on copolymer types involving silicone units with a very considerable variety of units based upon other multivalent elements. However aware we might be, that the possible in-

NO WONDER SOME STUDENTS ARE PERPLEXED...

LEARNING ISN'T EASY!

Here are some books designed to make it less difficult!

New (3rd) Edition!

Routh's 20th CENTURY CHEMISTRY

For the non-science major

Because students taking only one course in chemistry need a different approach to the subject than the chemistry major, Dr. Routh has designed his text solely for the one-year introductory course in the fundamentals of chemistry. Instead of the conventional study of inorganic chemistry, he gives an orderly and interrelated presentation of all three fields—*inorganic*, *organic* and *biological* chemistry. Principles are presented in a manner to provide a sound scientific basis of chemistry as applied to daily life.

For this *New (3rd) Edition* the author has rewritten and re-illustrated almost the entire book—integrating many interest-provoking examples of current advances in such topics as: lubricants for rockets and missiles; applications of radioisotope research; relation of RNA, DNA, and ATP to the mechanism of protein synthesis by the cell.

By Joseph I. Routh, Ph.D., Professor of Biochemistry, State University of Iowa. 489 pages, $6^3/_4'' \times 9^3/_4''$, with 282 illustrations. $8.00.
New (3rd) Edition!

Two New Programed Texts

Carnell & Reusch's MOLECULAR EQUILIBRIUM

This is the initial unit of a series on General Chemistry, one of the first programed courses in chemistry for freshman. *Molecular Equilibrium* presents, at a rigorous yet workable level, a subject area that beginning students have found most difficult to grasp.

The student learns more quickly and at his own pace as he follows through the question and answer frames of this program, building his knowledge of the subject step-by-step. The authors completely cover the subject in sections such as: *Reversible and Irreversible Reactions—Static vs Dynamic Equilibrium—Heterogeneous Reactions—Stress—The Role of the Catalyst—Le Chatelier's Principle—The Effects of Change in Temperature—etc.* A complete problem section at the end of the book tests student comprehension. The text was widely tested in over a dozen schools and with more than 200 students.

By Paul H. Carnell, Ph.D., Chairman, Department of Chemistry, Albion College, Albion, Michigan; and Rosetta N. Reusch, Ph.D. 217 pages, $7^1/_4'' \times 10''$, illustrated. $2.25. *New!*

Christensen's pH AND DISSOCIATION

Here is a remarkable new source of learning—to help students better understand the association and dissociation of the hydrogen ion in aqueous solutions. The text sets forth information in small sequential steps and requires the student to fill in the right answer before proceeding. The author presupposes only minimal acquaintance with pH, logarithms, indicators, titration, stoichiometry and structural chemistry.

After approximately 7 hours of study the student can expect to reach a level where he can calculate the pH of buffer systems, select indicators and buffers for various applications, interpret the titration curves of multifunctional compounds, predict the electrophoretic behavior and interactions of protein molecules, and understand the buffering by biological systems and the sensitivity of biological events to the pH.

By Halvor N. Christensen, Ph.D., Professor of Biological Chemistry and Chairman of the Department, The University of Michigan. 60 pages $7^1/_4'' \times 10^1/_4''$, illustrated. $1.75. *New!*

organic polymer types are enormously many, these two chapters must leave us gasping at the prospect of the unimaginably more numerous copolymer combinations.

The final chapter, by C. N. Kenney, quite briefly discusses some polymer types based upon metal chelation—wherein the chain and ladder-type connections are primarily organic. Again one gains a vista of extreme possible complexity, as the variety of organic patterns combines with the versatility of coordination chemistry.

On the whole, this book serves to open minds to wide areas of chemistry not often met in university courses, and demonstrates how important it is for students to develop a very sound background in inorganic chemistry even though they may intend to pursue other specialties. The main intent of the book is more descriptive than theoretical, but the authors are people having intimate experience with their subjects, and their basis for understanding quite frequently enters the discussion.

ANTON B. BURG
University of Southern California
Los Angeles

Introduction to Polymer Chemistry

John K. Stille, University of Iowa, Iowa City. John Wiley and Sons, Inc., New York, 1962. xi + 248 pp. Figs. and tables. 15.5 × 23.5 cm. $6.95.

This book is designed as an introductory text in polymer chemistry. Numerous subtopics are included under each major topic, and the table of contents includes these subtopics with page numbers for convenience of the casual reader, or for use of the book as a ready reference.

While the physical chemistry and characterization of polymers are discussed briefly, this book treats polymer chemistry predominantly from the organic chemist's viewpoint. Numerous references are cited for adequate sources of rigorous treatment of the various physical aspects of polymer chemistry, however.

The teacher of organic or physical chemistry who would like to give his students a more thorough background in the organic reactions which are capable of leading to high polymers as well as the physical aspects of polymers could well use this book as a supplementary textbook. In addition, practicing chemists or chemical engineers beginning a synthetic program in polymer chemistry would find the information supplied by the author on the various polymerization reactions as well as the reference material quite useful. Use of this book as a text for a beginning course in polymer chemistry, either at the advanced undergraduate level or at the graduate level, provided the lecturer supplements the material from the various specialized sources or from the current literature, is certainly appropriate. The excellent treatment of classical and mod-

WILEY BOOKS

including INTERSCIENCE

ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY, 2nd Edition, Vol. 2

Editorial Board: HERMAN F. MARK, *Chairman, Polytechnic Institute of Brooklyn;* JOHN J. MCKETTA, JR., *The University of Texas; and* DONALD F. OTHMER, *Polytechnic Institute of Brooklyn. Executive Editor:* ANTHONY STANDEN, *Interscience Publishers.* Volume 2 in the second edition of a reference work hailed as the most comprehensive and authoritative treatment of the American chemical industry. It is completely revised and rewritten, contains a host of new articles, and takes into account the most recent advances and up-to-date research carried out in all fields of chemical technology. An Interscience book. *Subscription price per volume: $35.00. Single volume price: $45.00.*

INTRODUCTORY TOPICS IN THEORETICAL PHYSICS: Relativity, Thermodynamics, Kinetic Theory, and Statistical Mechanics

By ROALD K. WANGSNESS, *University of Arizona.* An up-to-date and highly readable discussion of subjects in classical physics which are essential for the modern scientist. An outstanding feature of the book is the depth of exposition attained without the use of exceptionally complicated mathematics. The special relativity material is developed from electrodynamic considerations in a clear and straight-forward manner. *1963. In Press.*

INTRODUCTION TO THEORETICAL PHYSICS

By ROALD K. WANGSNESS, *University of Arizona.* A solid introduction to classical mechanics and electromagnetism, written in a clear and easy-to-read style. The choice of topics is restricted to those considered essential for a firm grasp of theoretical physics. Strong emphasis is placed on the normal mode concept, which makes the transition to the mathematical aspects of quantum mechanics much easier. *1963. 413 pages. $9.75.*

TRANSACTIONS OF THE SOCIETY OF RHEOLOGY, Vol. VII

Edited by E. H. LEE, *Stanford University.* Comprises the majority of the papers presented at the thirty-third annual meeting of the Society at Johns Hopkins University, Baltimore, Maryland, October 29–31, 1962. Abstracts are included of papers not printed in full, with reference to the complete paper where this is available. A symposium on Problems Common to Hydrodynamics and Hemodynamics is included. *1963. 428 pages. Paperback: $13.50.*

TREATISE ON ANALYTICAL CHEMISTRY, Part 1, Volume 5

Edited by I. M. KOLTHOFF, *University of Minnesota, and* PHILIP J. ELVING, *University of Michigan.* The latest in a series which presents a unified, critical and stimulating treatment of the theory of analytical chemistry. This volume covers optical methods of analysis, and includes articles on spectrophotometry, fluorimetry, X-ray methods, microwave spectroscopy, nephelometry and turbidimetry. *1963. In Press.*

EQUILIBRIUM STATISTICAL MECHANICS

By FRANK C. ANDREWS, *University of Wisconsin.* This book is a completely fresh approach to equilibrium statistical mechanics, with emphasis on mathematical simplicity and physical insight. The author uses a completely new organization of material to enable the reader to fully understand the reason for fundamental principles. Problems are an important part of the book and have been carefully chosen to illustrate topics discussed in the text, to show applications, and to encourage independent thinking. *1963. Approx. 208 pages. Prob. $5.00.*

ON PHYSICAL ADSORPTION

By SYDNEY ROSS, *of Rensselaer Polytechnic Institute, and* JAMES P. OLIVIER, *Southern Clays, Inc., Gordon, Georgia.* Deals with physical adsorption at the gas-solid interface, emphasizing experimental techniques and the treatment of experimental data. It shows how to determine surface area, surface heterogeneity, adsorbate-adsorbate interactions and surface-gas adsorption potentials from measured isotherms. These calculations are made easier by a special feature of the book—100 computed tables, printed as an appendix, and a number of illustrative examples. An Interscience Book. *1963. In Press.*

THIN FILM CHROMATOGRAPHY

By E. V. TRUTER, *University of Leeds, England.* A timely, concise book which provides a comprehensive description of qualitative analysis for thin film chromatography. It also explains special techniques required for resolving "difficult" mixtures, for carrying out quantitative analyses, and for preparing small amounts of pure material. A review of the literature up to 1962 is included. An Interscience Book. *1963. 205 pages. $7.00.*

ORGANIC CHEMISTRY, Fourth Edition Volume One: The Fundamental Principles

By I. L. FINAR, *Northern Polytechnic, Holloway, London.* The first volume in a new edition of a well-known text and reference. Many sections have been expanded, including those on resonance, free radicals, 1,2-shifts, substitution at a saturated carbon atom, hyperconjugation, aromaticity and aromatic substitution. Additional material includes shapes of molecules, transition of configuration, neighboring group participation and molecular overcrowding. Particularly important is the large expansion of the sections dealing with mechanisms. *1963. 853 pages. $9.50.*

ZONE MELTING OF ORGANIC COMPOUNDS

By E. F. G. HERINGTON. A clearly-written and lucid exposition of the latest information available on the zone melting of organic materials. The growing importance of zone melting as a versatile separation technique makes this book particularly timely and valuable. In the first chapter, the author provides a short history of zone melting and refining. In later chapters, he discusses the certification of the purity of samples, the manipulation of specimens, and some applications of zone melting. An Interscience Book. *1963. 162 pages. $5.95.*

BEL-ART

A COMPLETE LINE OF

filtering aids

BUECHNER FUNNELS

Seven sizes taking filter paper from 42.5 mm through 240 mm . . . molded in two parts of high temperature Polyethylene. The bowl and filter plate section has equal distribution of 1 mm holes in a circular pattern; smooth edges. The funnel and stem can be separated for easy cleaning. The two parts snap together for vacuum seal.

FIBERFILM FILTERS

A new approach to filtration, FIBERFILM.† Made of sub-micron glass fibers impregnated with TEFLON*; combines superior speed, clarity and tensile strength in a single filter material and adds filter features never before available. Extraordinary resistance to chemicals and heat; unprecedented rapidity of flow; dependable, specific pore size of 2-7 microns in diameter; no loss of strength when wet.

*DuPont's TFE Fluorocarbon Resin
†Reg. TM Amer. Machine and Foundry Co.

POROUS POLYETHYLENE SHEETS

High density Polyethylene with an average pore size of 50 microns. For filtration of corrosive solutions, air filtration and usage in chromatography, ion exchange columns, electrolysis, etc. Available in sheets 12″ x 12″ in various thicknesses or fabricated to order.

See your laboratory supply house.

BOOK REVIEWS

ern approaches to polymerization reactions, and the nature, structure and chemistry of initiators in vinyl polymerization, make the book particularly adaptable to use in organic chemistry courses. Among the topics of recent interest discussed under the conventional condensation polymer systems are the polyimides, polyimidazoles, and polytriazoles, structures which possess high thermal stability.

The separate discussion of polymerization by ring-opening reactions is a particularly novel approach to these systems. While, in general, these reactions can be considered as a special class of addition polymerizations, they are more easily understood by the novice in the field when summarized as the author has done, and treated as a class. A special class of polymerization reactions are discussed separately, predominantly because they do not lend themselves to easy classification among the well-known broad classes.

The various types of vinyl addition polymers are discussed mainly from a structural standpoint although the preferred initiator systems for each type are included. Also, as supplementary information for the reader of this chapter, information on the various types of initiator systems is presented in the discussion of mechanisms and kinetics of polymerization.

The brief treatment of naturally occurring polymers includes some excellent illustrative material. In general, the format and illustrations are excellent, and the reader is given some insight into the three-dimensional nature of polymer systems which is not readily apparent from many other sources of information. An excellent treatment of stereoregularity in polymers is also included.

University of Florida
Gainesville

An Introduction to Polymer Chemistry

W. R. Moore, Bradford Institute of Technology, England. University of London Press, Ltd. (published in U.S.A. by Aldine Publishing Co., Chicago), 1963. 270 pp. Figs. and tables. 14.5 × 22.5 cm. $7.50.

In the preface, the author makes the following statement: "There are many textbooks and monographs, often rather expensive, which deal at an advanced level with the physical and organic chemistry of high polymers and with specialized aspects in these fields. Reasonably compact and moderately priced books providing an introduction to the rapidly expanding field of high-polymer chemistry are less common. This text, based on lectures given by the author and his colleagues at post-graduate and undergraduate levels. . . is an attempt to provide such a book." A rather careful examination of the contents leads to the conclusion that the author has accomplished his purpose very well. The topics discussed, following a brief introductory chapter are the following: poly-

THROW-AWAY CARTRIDGE
DE-IONIZER
PRODUCES CHEMICALLY-
PURE WATER
RIGHT FROM THE TAP

INSTANT PURIFIED WATER

Open the tap or unclamp the tubing — you get chemically-pure water *at once.* Run only as much as you need — a few ounces or a bottle-full.

CHEMICALLY EQUIVALENT TO TRIPLE-DISTILLED

Note the purity of effluent shown in specifications below. De-ionized water is accepted by U S Pharmacopoeia as equivalent for all but injection solutions.

USED ONLY WHEN NEEDED

With this Cartridge De-Ionizer, your pure water is actually "on tap." You can come back for more at any time — it's always available. Flow rate is generous — 5 gph.

CONVENIENT — EASY TO INSTALL

You snap the Cartridge into the Wall Bracket, or clamp it into the Mounting Fixture. The resin changes color as exhausted — a clear line shows how much capacity remains. Write for Bulletin CD-161 giving full details.

RESEARCH MODEL	UNIVERSAL MODEL
Removes all ionizable solids including silica and CO_2. Average in effluent less than 0.5 ppm total solids.	Removes all ionizable solids, except silica and CO_2. Suitable for general pure water needs.
Capacity, 500 grains as $CaCO_3$.	**Capacity,** 1000 grains as $CaCO_3$.
Flow Rate, 5 gph max.	**Flow Rate,** 5 gph max.
Price, $12.50	**Price,** $9.75

WALL BRACKET with slip-on connection to water faucet $7.50
MOUNTING FIXTURE, clamp-in type for line-pressure use $12.00

CRAM
HAMMOND

ORGANIC CHEMISTRY / NEW SECOND EDITION

A superb NEW SECOND EDITION of ORGANIC CHEMISTRY by DONALD J. CRAM, Professor of Chemistry, University of California at Los Angeles; and GEORGE S. HAMMOND, Professor of Chemistry, California Institute of Technology WILL BE READY FOR SECOND SEMESTER CLASSES. Why a new edition? To make the book easier to understand, easier to use and, above all, easier to teach. The authors say "our greatest ambition in writing this book has been to bring students in their first course closer to the frontiers of organic chemistry. We hope that our organization eliminates the waste usually involved in reorientation of students' thinking when they pass from an elementary course either to an advanced course or to research. If this book serves these purposes, we have succeeded." To be more specific, the introductory material has been expanded from 4 to 7 chapters to clarify the explanations of the foundations. The sequence of the middle chapters on organic reactions has been systematized, proceeding from topics of general importance to more specialized. A major improvement is the use of two colors in the printing of the book, enabling the student to follow at a glance the active group in a chemical reaction. In addition to improving the presentation, the text has been completely updated. A new chapter explicitly treats the techniques of solving synthetic problems. New research data has been incorporated where appropriate. Write now to reserve your examination copy.

GODFREY STEREOMODELS FROM WILL SHOW SKELETAL STRUCTURE... MEASURE INTERNUCLEAR DISTANCES!

For teachers, students and research chemists.

*Can you match these stereomodels with their correct names? See column below!**

GODFREY STEREOMODELS present chemical relationships better than ever before possible. You can see skeletal structure . . . how atoms are linked . . . whether they are stable . . . and why. You can even measure internuclear distances with remarkable accuracy . . . a precise, 250,000,000X magnification of all elements is ingeniously maintained (2.5 cm. = 1Å). Bond angles are correct, too. Elements are all vividly, solidly and permanently colored throughout . . . and virtually unbreakable, too! Free rotation about single bonds is demonstrable . . . yet structures will remain locked in any pre-set position. Boat or chair conformations of cyclohexane show their natural stability . . . even intermediate twist conformations can be fixed in position for handling and measurement.

The basic kit is supplied, at no extra charge, with a large variety of structural components . . . olefinic and aromatic double bonds, acetylenic triple bonds, the benzene ring, amide and nitrile groups, as well as tetrahedral and trigonal carbon and nitrogen, digonal oxygen and sulfur, hydrogen and the halogens . . . *at a price one-third of any competitive unit.* No tools are required for assembly . . . simple, quick, hand connections only. Connector tubes have positive, snaplock connections, with built-in torsional friction. Large, complex models (synthetic polymers, proteins, polysaccharides) can be assembled and handled without falling apart.

*

STEREOMODELS IN TOP PHOTO:

A. Methylacetylene

merization, the structure and properties of polymers, the interaction of polymers and liquids, synthetic organic addition polymers, synthetic organic condensation polymers, inorganic and semi-inorganic polymers and natural organic high-polymers.

Each of the topics discussed, if treated exhaustively, would occupy several volumes, and such volumes are available; however, the discussion included here is adequate for the beginner in polymer chemistry, either as a student of chemistry or chemical engineering at the undergraduate level or as a research chemist in the laboratory beginning a program of synthetic polymer chemistry or a study of polymer properties. Numerous references are included to introduce the reader to these valuable treatises on the various subjects. The biochemist interested in becoming more familiar with the chemistry of the synthetic counterparts of the naturally occurring high polymers which he deals with largely will find this book of considerable value.

The teacher of organic or physical chemistry at either the graduate or undergraduate level would find this book quite useful as a supplementary text for introducing the subject of high polymer chemistry to his students. As a text for a course in high polymer chemistry at either the advanced undergraduate or graduate level this book would be ideal, provided appropriate supplemental material either from the wealth of specialized topics sources or from the current literature were used.

The format and illustrations are pleasing to the reader, and topic headings within each chapter are set apart for easy location by the casual or rapid reader.

The various methods of determination of molecular weights and other physical properties of polymers are discussed briefly and the fundamental theories presented. Little detail as to the experimental procedures necessary for carrying out these operations in the laboratory is given, but reference material is cited. The tremendous importance of stereoregularity in polymers is perhaps not sufficiently emphasized in the book, although a discussion is presented. Numerous interesting and potentially important polymer systems are omitted. For example, the "1-nylons" derived from anionic polymerization of organic isocyanates are not discussed; however, such recent copolymers as the tetrafluoroethylene-trifluoronitrosomethane copolymers are briefly referred to.

A SELECTION OF STIMULATING CHEMISTRY TEXTS FROM MACMILLAN

INTRODUCTORY CHEMISTRY

Third Edition

By **Lillian H. Meyer,** Western Michigan University

The new edition of Dr. Meyer's text is remarkable for the clarity of its presentations. Avoiding unnecessary scientific jargon, the book uses examples from particular fields of interest, such as home economics and the biological sciences, to stimulate interest among non-chemistry majors. In addition to these illustrative examples, there are chapters on glass and pottery and leavening agents which demonstrate the practical application of material from the course. The first part of the book introduces students to the concepts and the quantitative aspects of chemistry. The second part offers a unique treatment of textile chemistry and a more thorough discussion of organic chemistry than most introductory texts. Illustrations are numerous, and definitions and important terms are italicized.

To be published in Spring, 1964

LABORATORY MANUAL FOR INTRODUCTORY CHEMISTRY

Revised Edition

By **Lillian H. Meyer**

The accompanying manual for *Introductory Chemistry* provides a brief but thorough account of fundamental procedures and a carefully selected list of experiments. It differs from other introductory manuals in that there are several experiments adapted from biochemistry and illustrative experiments from textile chemistry.

To be published in Spring, 1964

THE CHEMISTRY OF ORGANIC COMPOUNDS

Fifth Edition

By **James Bryant Conant,** President Emeritus, Harvard University, and **Albert H. Blatt,** Queens College

Designed for the first course in organic chemistry, this compact text offers enough material for a terminal course and provides a good foundation for those who will take advanced courses. The book follows the desirable and eminently effective practice of introducing concepts in relation to their applications. Important mechanisms are discussed in connection with reactions to which they apply, and bond types in connection with structures containing them. The Fifth Edition features an order and method of presentation that has been classroom-tested for efficiency. It opens with a discussion of isomerism, structure, and valence, and then proceeds to the hydrocarbons. The chapters that follow systematically present the material normally used in a year-length course. Four specialized chapters on Derivatives of Carbonic Acid, Compounds Containing Sulfur, Natural and Synthetic Drugs, and Some Biochemical Processes enable the individual instructor to satisfy some special interests. The book is amply illustrated.

1959, 652 pages, $8.25

QUANTITATIVE CHEMICAL ANALYSIS, Twelfth Edition

By **Leicester F. Hamilton** and **Stephen G. Simpson**, Massachusetts Institute of Technology

The authors have revised and expanded the new edition of this highly successful text to incorporate new material on coprecipitation, ion-exchange, electrode potentials, electrolysis, acids, bases, and salts. In recognition of the growing number of colleges that offer quantitative analysis as a sequal to a course in organic chemistry, the authors have provided a new body of illustrative material. They include determinations that show how analytical techniques can be applied to the determination of organic functional groups such as the hydroxyl, phenol, nitro, and amino groups. Many problems have been reworded for greater clarity or conciseness, and all answers have been combined to form a separate section of the book.

To be published in Spring, 1964

GENERAL CHEMISTRY
A Systematic Approach, Second Edition

By **Harry H. Sisler,** University of Florida, **Calvin A. Vander Werf,** Hope College, and **Arthur W. Davidson,** University of Kansas

This is a thorough, inductive approach to the basic principles of college chemistry, with accent on careful, step-by-step reasoning in which nothing can be taken for granted. It includes many current topics that are sure to interest today's students, such as recent developments in the chemistry of rare elements, rocketry and satellites, medicine, applied organic chemistry, plastics, and new industrial processes. The guiding and unifying principle is the structural basis of the properties of matter. Descriptive material is organized in terms of periodic families, and the correlation of fact with theory is consistently emphasized. Unusually extensive problems and drill questions provide excellent practice for students, and there are many fine illustrations. *1959, 861 pages, $8.50*

COLLEGE CHEMISTRY
A Systematic Approach, Second Edition

By **Harry H. Sisler, Calvin A. Vander Werf,** and **Arthur W. Davidson**

Based on the chemical bond approach, this text is an entirely self-contained presentation of the principles of modern chemistry. It differs from *General Chemistry* in that the treatment is shorter and more direct. Its coverage includes the very latest important developments, including molecular orbital theory, life chemistry, and chemistry in outer space. The unusually thorough treatment of the metals is especially useful for engineering students, and there is greater emphasis on reaction rates and activation energies than in the previous edition. More than 700 problems and questions are included—an unusually large selection for a text of this kind.

1961, 719 pages, $7.95

A SYSTEMATIC LABORATORY COURSE IN GENERAL CHEMISTRY, Second Edition

By **Harry H. Sisler, Jay Stewart,** E. I. duPont de Nemours & Co. Inc., and **W. T. Lippincott,** University of Florida

Designed to accompany either *General Chemistry* or *College Chemistry*, this manual assembles experiments that emphasize both quantitative aspects and broad general coverage of introductory chemistry. *1961, 369 pages, paper, $4.25*

THE MACMILLAN COMPANY

3rd Edition EXPERIMENTS IN GENERAL CHEMISTRY

Revised this year, this manual contains some 30 experiments that emphasize principles rather than descriptive matter. Most of the experiments are quantitative. Problems for solution follow each experiment.

It covers up-to-date topics as well as the classics. A water analysis that includes an E.D.T.A. titration and an experiment on atomic spectra are two unique features. Also included are demonstrations by the instructor for schools with limited equipment.

by J. B. Nordmann and E. S. Kuljian 156 pages, $3.50

ORGANIC CHEMISTRY LABORATORY EXERCISES

Meets the needs of chemistry majors, engineers, pre-medical students taking a beginning organic chemistry course two or three quarters or two semesters long.

Experiments use one-tenth the amounts commonly used. The equipment is conventional but smaller in size. The laboratory is safer, less space is required, equipment and chemicals are more economical.

by James M. Sugihara 128 pages, $4.00

THE NATURE AND USES OF MODERN FUNGICIDES

A ready reference on specific prescriptions for plant disease control, supplemented by usable technical data on specific fungicides. Contains reference conversion tables and normographs.

by Eric G. Sharvelle 311 pages, $6.00

chemistry at the undergraduate level, based on their experience in teaching students with a wide range of major interests and widely varying preparations. They have written a short but comprehensive, well-integrated book to support such an objective. While it is not designed specifically as a preparation for advanced work, it will open interesting vistas and may well stimulate a desire for a more rigorous consideration of topics here touched lightly.

"Certain aspects of organic chemistry . . . particularly important for a clear understanding of the structures, functions, and reactions of various compounds of biochemical importance. . . have been selected for very brief review and re-analysis" in Chapter 1.

In the discussion of the chemistry of the proteins, amino acid and peptides, the carbohydrates, the lipids, and nucleic acids and the nucleotides, "only those details most necessary for the comprehension of the processes of metabolism and the research methods of the biochemist" are presented. "Much material traditionally included in introductory courses has been omitted." In the light of their objectives, their selection is good.

One would trust that the instructor using this textbook would refer to or even go deeper into the chemistry of biochemical materials and the chemical aspects of the reactions described, to provide comprehension of processes and methods subsequently to be discovered or introduced on the rapidly advancing frontiers of biochemistry. The abler and better prepared student should then be stimulated to further reading and be better able to make productive applications of biochemical approaches to the problems in his own area of major interest.

The brief discussion of enzymes, essentially descriptive, while simplified, is quite good. They state, correctly, "the naming of enzymes has not yet become standardized" without, however, reference to the recommendations presented in the recent Report of the Commission on Enzymes of the International Union of Biochemistry. Since, " in many succeeding reactions the names of the enzymes will be ommitted for simplicity," a fuller presentation of the naming of the enzymes would be valuable.

The authors present briefly, but clearly, with formulas, equations and diagrams, the essentials of the intermediary metabolism of the carbohydrates, lipids, proteins, and amino acids, and the biosynthesis of these substances, and of the purines, pyrimidines, and urea. They have made a successful endeavor to bring the material up-to-date. The student is given briefly a basic acquaintance with a great variety of related and pertinent topics.

The authors recurrently emphasize inter-relationships in the processes of metabolism and the coordinated control of these. They bring out explicitly interpretations that are not commonly presented except by implication. The book bears evidence that it is the product of interaction between students and teachers. With each chapter there is a well-selected

A GREAT NEW WORK . . . FROM AMERICAN ELSEVIER

VAPOR PRESSURE OF CHEMICAL ELEMENTS

By A. N. Nesmeyanov, Director, Institute of Organo-Element Compounds, and President, USSR Academy of Sciences, Moscow

Edited by Robert Gary, National Bureau of Standards, Washington, D. C.
(*Translated by Scripta-Technica, Inc., Washington, D. C.*)

7 × 10″, 471 pages, plus Index, 152 illustrations, 369 tables.....Price: $17.50

This book fills a long-standing need for a book on Vapor Pressure of Chemical Elements. Professor Nesmeyanov, as one of the foremost leaders in Russian science, speaks with considerable authority in this great new work.

The book constitutes a critical evaluation of all data on the elements available to the author, with the exception of hydrogen, nitrogen, oxygen and the "inert" gases, which present special problems and are treated elsewhere.

Theory and methods of measurement are discussed in the first chapter, and the data are presented in tabular and graphic form. Coefficients for equations relating to vapor pressure and temperature were computed by machine on the basis of the best data, and the results are tabulated in an Appendix. The book is thus well adapted as a handbook.

Editor Robert Gary, of the National Bureau of Standards, has adapted the numerous tables to the specifications and uses of American equipment.

This book will be an essential reference work for all chemical engineers, chemical and pharmaceutical laboratories, and scientific and technical libraries.

THE COMPLETE SET IS STILL AVAILABLE . . .

CHEMISTRY OF CARBON COMPOUNDS

Edited by E. H. Rodd, with a distinguished Advisory Board

"There is no question that the 'Chemistry of Carbon Compounds' series will remain *the* outstanding medium-sized compilation or organic chemistry for many years to come."

—William A. Bonner, Stanford University
(*Aug. 1963 review in Journal of Chemical Education*)

This unique reference work bridges the gap between encyclopedias and textbooks. For the working organic chemist it provides authoritative information. It is invaluable to scientific libraries, technical schools, colleges, and industrial laboratories.

brief list of references for "suggested additional reading."

This book may be commended warmly to the attention of those teaching biochemistry as a terminal course for those undergraduate students, not highly trained in chemistry, who would otherwise fail to encounter biochemistry as a separate discipline.

RALPH C. CORLEY
Purdue University
Lafayette, Indiana

On Divers Arts: the Treatise of Theophilus

Translated by *John G. Hawthorne*, University of Chicago, and *Cyril Stanley Smith*, Massachusetts Institute of Technology. University of Chicago Press, Chicago, 1963. xxxv + 216 pp. Figs. and tables. 17.5 × 25 cm. $8.50.

The increased interest in the history of technology during the last few years is continuing to be a stimulus for the publication of scholarly translations into English of important technological texts written in medieval Latin, old Italian, old German, and other difficult languages. The present volume is a welcome addition to the small group of English translations of treatises which deal more or less with chemical technology. The present work also is of special interest since it marks the cooperative effort of the well-known metallurgist and historian, Cyril Smith, with a well-known classicist.

Theophilus is thought to be the pseudonym of a German metalworker and Benedictine monk, Roger of Helmarshausen. Theophilus' treatise written in medieval Latin is particularly important for the history of chemical technology, since it has been well established that the writer of the treatise was a practical worker in the arts which he describes and not just a compiler of recipes as was common with most authors of medieval treatises on technology.

Theophilus was not a scientist in our modern sense but a technologist skilled in the best techniques concerned with the manufacture, preparation and mixing of pigments for painting, the making of glass and in special methods of metal working. The translators of this work point out that while Theophilus' treatise has been well known to art historians because of the detailed discussion of paint making, they have also emphasized in detail the instruments and techniques used for glass making and metal working. The translators have reconstructed many of the instruments and apparatus described by Theophilus and have illustrated these and their method of operations by drawings. Detailed bibliographical information on the various texts and translations of Theophilus' treatise are presented and a number of fine illustrations in addition to the drawings of the reconstructed instruments and apparatus

SYNTHESIS OF ORGANOSILICON MONOMERS

BY A. D. PETROV, V. F. MIRONOV, et. al.
Translated from Russian

". . . an invaluable addition to the American reference literature of chemistry for which we shall long be grateful."

Dr. Eugene G. Rochow
FROM THE FOREWORD

Concentration is on synthesis reactions for the preparation of organosilicon monomers. Gives a general review of the synthesis and properties of organosilicon compounds, together with a thorough coverage of unsaturated organosilicon compounds, aromatic organosilicon compounds, and organosilicon hydrides respectively.

Approx. 575 pages **$22.50**

ANALYSIS INSTRUMENTATION - 1963

Proceedings of the Ninth (1963) National Analysis Instrumentation Symposium.

EDITED BY DR. L. FOWLER, R. D. EANES, AND T. J. KEHOE

An expert evaluation of the state-of-the-art, drawing upon the skills of leaders in analytical and process instrumentation to present an immediate picture of the current state of development of this fast growing field. Data on a variety of new and proposed devices and applications have been provided by experts actively at work in some of the best-known plants and laboratories in the world, resulting in a truly unique survey of analytical automation. From the thirty top technical papers published in the volume, trend setting new systems include: the Lunar Gas Chromatograph, an All-Solid-State pH Meter, and a Microwave Moisture Measuring Instrument. Additional topics include determination of polymer molecular weight distribution by "gel permeation chromatography", the development of automatic data processing techniques for chromatographic analysis, infrared analysis of vapor phases of substances with low vapor pressures at room temperature, and the open-path infrared area monitor for toxic vapors.

272 pages **$12.50**

INFRARED BAND HANDBOOK

BY DR. HERMAN A. SZYMANSKI, CHAIRMAN, CHEMISTRY DEPARTMENT, CANISIUS COLLEGE

Over 8500 band positions of organic and inorganic compounds tabulated according to wavenumber of their IR spectral absorption bands. Data retrieval time is substantially cut as all compounds with absorption at a given wavelength are listed sequentially, and the formula cross index lists all bands produced by compounds. The range of wavenumbers presently covered is 3610 to 617 cm^{-1}. Supplements will extend this range to 250 cm^{-1}. Information on sampling technique, instrument resolution, group vibration responsible for the band, and band intensity is also listed when included in the original source. Single band entries as well as complete spectra are included. Complete literature references are provided. Sample pages upon request.

496 pages **$35.00; supplements, $7.50**

GUIDE TO GAS CHROMATOGRAPHY LITERATURE

BY AUSTIN V. SIGNEUR, CANISIUS COLLEGE

Documents the entire range of gas chromatography literature with some 7000 references from the earliest investigations to early 1963. All entries are cross-indexed by subject as well as being arranged by author — the only single-volume publication to be set up in such a manner. Wherever possible, reference is given to Chemical Abstracts so that the worker may obtain further information. Complete pagination is supplied for procurement of microfilm or photostatic copies of the original article. This is the largest and most comprehensive work of its type ever published.

250 pages **$12.50**

ADVANCES IN GLASS TECHNOLOGY PARTS 1 & 2

PART 1

Technical Papers from the Sixth International Congress on Glass, July 8-14, 1962, Washington, D.C., Sponsored by the International Commission on Glass, in Cooperation with the American Ceramic Society.

EDITED BY GUY E. RINDONE

". . . the range of subject matter and the quality of the contributions are such that no glass technologist desiring to keep abreast of this diversified and expanding field should neglect the thorough study of this timely contribution."

CERAMIC ABSTRACTS

". . . a mammoth undertaking and a job extremely well done . . ."

THE GLASS INDUSTRY

48 papers by leading scientists from glass and ceramic societies and research institutes throughout the world, each paper prefaced by abstracts in English, French, and German. Reports cover a broad range of new developments in glass science, technology, manufacturing, and design. Both theoretical and experimental results of extensive research are presented and discussed. Selected topics are balanced between fundamental, applied, and engineering studies.

661 pages **$21.00**

PART 2

Additional Papers from the Sixth International Congress on Glass.

EDITED BY FREDERICK R. MATSON AND GUY E. RINDONE

108 contributions advancing coverage begun in Part 1. New technical papers are: Experimental Basis for Classification of Oxides According to Their Influence on the Surface Tension of Silicate Melts; New Types of Glasses Showing Electronic Conductivity; Physiochemical Properties of Germanium Glasses; Orientation Effect and Shape Birefringence in Sodium Borosilicate Glasses; and Course of Fracture Propagation in Glass under Varying Strain. Contains full discussions of papers presented in Part 1, and Brief Research Announcements of new research projects now being undertaken. Includes 29 unique papers on the archeological, chemical, physical, and historical aspects of ancient glass, glass formed by meteoritic impact, and the social aspects of glass manufacture.

428 pages **$15.00**

are also included. Many technical notes by the translator make clear certain obscure passages.

It is to be noted that another English translation of Theophilus' treatise was published in 1961 under the authorship of C. R. Dodwell, and Dr. Smith and Dr. Hawthorne have exchanged a great deal of information with Dodwell.

This book is recommended to students of the history of technology of chemical arts, to art historians, and, of course, to bibliophiles and book collectors concerned with the history of technology.

New Volumes in Continuing Series

The following titles are those of volumes in continuing series. Many of these series are familiar to readers, who are best served by prompt announcement of the appearance of new titles. The policy of THIS JOURNAL will be to publish full reviews only of inaugural volumes in new series. The publication of later volumes will be announced in this column. Full bibliographic information will be supplied as well as a list of contributing authors.

Progress in Drug Research. Volume 4

Edited by *Ernst Jucker*, Basel. Interscience Publishers (a division of John Wiley and Sons, Inc.), New York, 1962. 606 pp. Figs. and tables. 17.5 × 24.5 cm. $30.

Contributors: Von H. Herbst; N. J. Harper; E. Schlittler, J. Druey, and A. Marxer; Von H. Grasshof; J. C. Arcos and M. Arcos.

Pentose Metabolism in Bacteria

B. L. Horecker, New York University School of Medicine, New York. John Wiley and Sons, Inc., New York 1962. vii + 100 pp. Figs. and tables. 13 × 19 cm. $4.

CIBA Lectures in Microbial Biochemistry: Oxidative Pathways; Fermentation Mechanisms; Enzyme Mechanisms in the Carbon-Carbon Cleavage Reactions.

Nouveau Traité de Chimie Minérale. Volume 20, Alliages Métalliques, Part 2

Paul Pascal, general editor. Masson et Cie., Paris, 1963. L + 1153 pp. Figs. and tables. 17.5 × 26 cm Broché, 200 NF; cartonné toile, 212 NF.

Contributors: M. R. Collongues; M. Oswald; P. Fauconnier and R. Lapassade; P. Pascal.

SEMI-MICRO SETS

for • EDUCATION
• RESEARCH
• INDUSTRY

- *Complete, Compact, Ready for Use*
- *Framework and Supports Included*
- *Low Cost and Minimum Breakage*
- *Cabinets Contain all Components*

The SCHUCO range of SEMI-MICRO apparatus provides simple, compact sets ideal for school use to sets giving over twenty different assemblies for post-graduates and the research worker. Unique features are the special portable cabinets complete with fittings, including acid resistant working base, rigid metal framework and micro burner. The clamp/bosshead attachments which support the glass apparatus eliminate traditional bossheads and clamps making the whole outfit a composite "ready-to use" apparatus needing no extras.

***Set No. E. S. 7:** Consisting of 16 components with ground joints. Complete with cabinet and framework... **$69.00**

***Set No. E. S. 8:** Consisting of 21 components with ground joints. Complete with cabinet and framework... **$84.00**

***Set No. E. S. 11:** Consisting of 6 components which can be used to supplement either set E.S. 7 or E.S. 8. Can also be used as simple introductory set. Complete without case or framework. **$13.00**

***Quantity Discounts:** 1-11 sets net, 12-23 sets 10%, 24-49 sets 15%, 50 or more sets 20%. Sets E.S.7 and E.S. 8 only may be assorted to earn quantity discounts.

Available from SCHUCO or your Lab Dealer.

SS

MICROSCOPE SCREEN

ONLY **$42**

A professional microscope screen—4″ x 5″—that can be mounted on any standard microscope

For General Medical Use • Research • Laboratory Education • Industrial Analysis

Brilliant, clear images of specimen material can be viewed in normal room light on the SS Microscope Screen, when illuminated with a high-intensity, transformer-powered illuminator. Fits standard 1″ eyepiece tubes.

The SS Microscope Screen will fit practically all microscopes having a standard diameter eyepiece tube, vertical, inclined, monocular, binocular or trinocular. Huygenian and wide field optics can be utilized for a larger image. High impact plastic, anodized aluminum construction. 4″ x 5″ unique, "black" viewing screen, grainless, with no hot spots. Adapter ring included for wide field optic.

Cat No. JC-72590—
Microscope Screen w/case and Adapter for 29 mm diameter lens tubes **$42.00**
Huygenian Eyepiece 10x **$11.00**

EBERBACH AUTOFRACTOR® FOR AUTOMATIC FRACTION COLLECTION

The new Eberbach explosion-proof AUTOFRACTOR collects liquid fractions in column chromatography of the absorption, ion exchange, or partition type. It is a volumetric syphoning type employing the force of gravity. A set of 6 syphons is provided and are adjustable up or down to correct for rate of flow from the column. No electrical power is required, providing greater safety when used in the presence of volatile solvents. The absence of electrical components minimizes the problem of maintenance and adjustment. Catalog No. 1700 for aqueous solutions and catalog No. 1705 for organic solvents, each $475.00. Request Bulletin 700

Interpretation of Mass Spectra of Organic Compounds

HERBERT BUDZIKIEWICZ, *Research Associate, Stanford University*
CARL DJERASSI, *Professor of Chemistry, Stanford University*
DUDLEY H. WILLIAMS, *Research Associate, Stanford University*

A remarkable number of books has appeared during the past three years dealing with certain chemical applications of mass spectrometry, and the obvious question may be asked: "Why another one and why now?" The first reason is that well over half the material covered in the present monograph has been published so recently, or is still unpublished, that it could not be included in the other texts. Second, none of the recent books are so organized as to deal exclusively with chemical structure, or even more importantly, with the presence of functional groups, which trigger or control the overall fragmentation process of the organic molecule. This is the gap that this book fills; at the same time, the authors call attention to the many groups of organic compounds which have not yet been subjected to mass spectral scrutiny. The utility of the book was emphasized when the manuscript was used as lecture notes in a graduate course on organic chemical applications of mass spectrometry taught by one of the authors at Stanford University.

The book is directed to the organic chemist—student or practitioner—who is considering using, or has used, mass spectrometry in his own problems and would like to get more information about what this tool can do for him. In particular, it will assist the organic chemist in the rational interpretation of mass spectra and enable him to extract the maximum amount of information from the fragmentation pattern of a given substance. The chapters are as follows:

1. ALIPHATIC AND MONOCYCLIC CARBONYL COMPOUNDS 2. ALCOHOLS 3. ETHERS, THIOETHERS AND MERCAPTANS 4. AMINES AND AMIDES 5. CYCLIC AMINES 6. ALIPHATIC CYANIDES AND ISOTHIOCYANATES 7. ALKYL HALIDES 8. BICYCLIC KETONES 9. AROMATIC HYDROCARBONS AND FUNCTIONAL DERIVATIVES 10. TROPONES AND TROPOLONES 11. AROMATIC HETEROCYCLICS

SPECIAL PREPUBLICATION OFFER: On postpaid orders received prior to January 15, 1964, Holden-Day is offering a special discount of 20% from the list price of $8.75 or $7.00. On prepaid orders received by this date, we shall extend a discount of 25% from the list, or $6.56. (Residents of California, $6.82, to cover 4% sales tax.)

Infrared Absorption Spectroscopy

KOJI NAKANISHI, *Tohoku University, Sendai, Japan*

From the *BRITISH BULLETIN OF SPECTROSCOPY:*

"The title of this book may mislead some people into supposing that it is just another text on instrumentation, cell construction and the like. This is not so. Professor Nakanishi is an organic chemist to whom 'practical IR spectroscopy' means (very sensibly) the use of spectra in the identification and characterisation of organic compounds. This is an introductory text designed to help the student along this path and it is indeed intensely practical. The best way to learn to interpret spectra is to get on with the job and this book provides an opportunity to do so, as two-thirds of it consists of specific problems which the reader is invited to solve . . . this is overall an excellent book which achieves very well what it has set out to do. It will serve an admirable purpose as an introductory text for the organic chemist and will give him an opportunity of familiarising himself with spectral problems in a way which cannot otherwise be easily done."

L. J. Bellamy, Brit. Bull. Spect. No. 52, pp. 248-249.
Price: $8.00, 10 or more copies prepaid, $6.00 per copy.

PROPIPETTE

Safety Pipette Filler

holds liquids indefinitely

- Time Tested
- No moving parts
- Simple to operate

The new PROPIPETTE eliminates the dangerous practice of using the mouth to draw liquids into pipettes. It is simple to use and the operator soon becomes proficient so that liquids can be delivered quickly, precisely and safely. Measurement precision is extremely high (0.01cc). The instrument has three agate-ball valves which operate independently and the entire procedure can be done with only one hand.

Choice of black, red, green, yellow and blue.....PRICE $7.60 each
Available through laboratory dealers. sent on approval

All laboratory pipettes can be used with the PROPIPETTE — Safety Pipette Filler

SUPPLEMENTARY READINGS FOR CHEMICAL BOND APPROACH

Complied by ROBERT K. FITZGEREL
and WILLIAM F. KIEFFER, *Editor*
JOURNAL OF CHEMICAL EDUCATION

"These articles continue from the point a textbook is forced to stop" . . . "You have under one cover the best collection of articles to stimulate students to seek answers on their own that I have ever seen" . . . "I am pleased to find so many of the excellent summaries of modern theory which have made the Journal indispensable to me and my students."

Comments like these have prompted our making available to an unrestricted market the volume of "Supplementary Readings" originally compiled for use as resource material by those engaged in the NSF-sponsored experimental course, "The Chemical Bond Approach."

Old friends of the Journal will find some classics such as Fernelius and Robey's "Metallic State" (1935), the DeVault series (1944), Campbell on "size" (1946), Noller on "orbitals" (1950), etc. New friends will find 1959 favorites such as the articles by Taube, Price and Kimball and Loebl.

Many modern interpretations of chemical bonding are developed further than usually found in textbooks. The variety of approaches is itself stimulating to the inquiring reader. The obvious feature common to the whole collection is that these have been written by authors whose successful experience with students has shaped their presentation.

the fine hands of architects, engineers and specifiers "powerize" laboratories with Lab-flo™ SCIENCE SERVICE FIXTURES

Like a power-rated engine gives predicted performance, LAB-FLO science service fixtures provide new vitality and greater service effectiveness for all types of laboratories. Leading school and industrial architects and specifiers recognize LAB-FLO as the ultimate in quality and reliability. That is why LAB-FLO has become the standard for most specifications and comparisons... and "or equal" finds practically nothing to challenge it. Complete, integrated LAB-FLO science service fixture lines and nationwide coverage offer distinct advantages to the laboratory planner. Write or call for Catalog No. 90-A.

LAB-FLO SPEC MANUAL

This dynamic LAB-FLO planning guide provides all of the newest drawings and data for roughing-in or specifying a complete laboratory service fixture system, or any part of it. Write or call today for your personal, registered copy.

PARR *Calorimetric Thermometers*

Have you ever examined a Parr calorimetric thermometer? If so, you have noticed the careful workmanship in the glass and the uniformly fine engraving. You have also seen the individual test certificate and correction chart which accompanies each instrument, reporting calibration against an NBS certified platinum resistance thermometer at a number of points along the graduated scale.

All Parr calorimetric thermometers are approximately 24 in. long, with 7.0 to 8.0 mm. dia. stems. They are made to rigid ASTM and Parr specifications, incorporating all of the features necessary for best accuracy in combustion calorimetry. Both F and C scales are available. Nos. 1611 and 1613 have NBS certificates, others are certified by Parr.

Klett Summerson

Photoelectric Glass Cell Colorimeter

No. 900-3

The Klett Fluorimeter

No. 2070

Designed for the rapid and accurate determination of thiamin, riboflavin, and other substances which fluoresce, in solution. The sensitivity and stability are such that it has been found particularly useful in determining very small amounts of these substances.

KLETT SCIENTIFIC PRODUCTS

BIO-COLORIMETERS • GLASS ABSORPTION CELLS

HELLER ELECTRONIC VARIABLE-SPEED

AC CONTROLLER and Matching DC MOTOR

2T60 ELECTRONIC CONTROLLER
with matching 1/50 H.P. DC MOTOR

$87
Complete, F.O.B., Las Vegas, Nevada

SPECIFICATIONS

• Thyraton tube operated controller gives stepless operation • Input: 110-120 V., 60 cy. single phase • Output: 0-120 V., 200 ma. DC to armature • 1/50 H.P. ball bearing, right angle, gear head, shunt wound, DC motor • Reversible • Armature shaft is extended • Armature speed 0 to 4000 R.P.M. • Motors in gear ratios: 6, 18, 30, 36, 60, 100, 300, 540, and 1120:1 in stock.

Other models to 3/4 H.P. motors available. Request data.

ANSELL-PLAX
all-polyethylene
WASH BOTTLES

SQUEEZE — THAT'S ALL

Get the stream you want. Can't break ...won't slip. It's unaffected by strong acids or alkalies. Specified for use by laboratories everywhere --government, institutional, industrial.

ONLY ANSELL-PLAX FIRST POLYETHYLENE WASH BOTTLE, HAS THE PATENTED* DISPENSING ASSEMBLY THAT MEANS

- NO LEAKING, SEEPING OR NECK SPRAY
- SPECIFY NO *SUBSTITUTES* WHEN ORDERING

4, 6, 8, 16 & 32-oz. sizes. Conveniently packed in individual set-up boxes and Polyethylene Bags. Call your lab supply house or write us directly.

*fitment covered by U.S. Patent #2783919

S. H. ANSELL & SON, INC.
825 Summer St., Boston 27, Mass.

SPECIFY **KERN**

When you must dialyze small quantities of solution, ask for KERN, a small Pyrex receptacle that completely dialyzes 1 ml. in 1 hour. Buffer filling and membrane can be used again. Dialysis can be done overnight if desired.

What readers say about

SELECTED READINGS IN GENERAL CHEMISTRY

Compiled by WILLIAM F. KIEFFER, Editor
Journal of Chemical Education

and ROBERT K. FITZGERALD
Kansas Junior College

- "... an extremely useful addition to my teaching aids."
- "... a fine idea, well concieved and well executed."
- "It has a very good blend of technical articles and articles which give a broad view of chemistry, and it should be of great interest and help to chemistry students and teachers."
- "... very interesting ... a fine start on what could develop into a series."
- "a handsome, interesting and very useful book."

TEN YEAR CUMULATIVE INDEX

JOURNAL OF
Chemical Education
Volumes 26 through 35
(1949–1958)

This index has been prepared with the special interests of the J.-Chem.-Ed. user in mind. Not only are the conventional entries made by author, title, and inverted title, but many suggestive subject listings have been used. For example, reference to an article entitled "Infrared Spectra of Chemisorbed Molecules" can be found under "acetylene," one of the compounds discussed. Preparation of the index involved hundreds of hours of careful checking not only of annual indexes, but the original articles for subject content.

For the busy teacher the index will be a valuable time saver. Students will find it to be an excellent place to start on a term paper assignment. For those preparing text or laboratory materials it will be an indispensable first-place-to-look for reference to both J. Chem. Educ.-type review articles and to reports of successful experiments in teaching. The more than 5000 subscribers who have begun their personal files of the Journal in recent years will find that this one small volume puts extra years of the "living textbook of chemistry" on their shelves.

$2.50 per copy
(Postpaid)

"I am impressed with your

COLLECTED READINGS in INORGANIC CHEMISTRY

and intend to use it as an auxiliary reference in two inorganic courses which I am teaching"

Inorganic chemical research is moving so rapidly that keeping abreast of developments is increasingly difficult for student and teacher. During the past five years many review articles written specifically to serve this purpose have appeared in the pages of the *Journal of Chemical Education.*

Twenty of the country's most prominent professors of inorganic chemistry indicated the articles they have found most useful; 41 of their most frequent choices have been collected in this volume. Various aspects of Coordination Chemistry are treated by 14 articles. Five deal with Inorganic Polymers, six with Non-Aqueous Systems, and five with topics in Solid State Chemistry. The remainder discuss miscellaneous topics from nucleogenesis to chromatographic behavior of metallic ions.

The popularity of these papers has been demonstrated by the demand for reprints, often far beyond the authors' supplies. The convenience and low multiple-copy price of this volume of collected papers makes it a most valuable supplement to existing textbooks. Every student can now have on his bookshelf the authors he recognizes to be authoritative specialists: Nyholm, Sutton, Bailar, Pearson, Eyring, Audrieth, Burg, Sisler, Honig, Coryell, and many others.

HITACHI PERKIN-ELMER ULTRAVIOLET VISIBLE GRATING SPECTRO-PHOTOMETER

The Model 139 Grating Spectrophotometer, a compact, precise modern instrument, out performs similar spectrophotometers costing significantly more.

Check these features: High resolution grating Monochromator — gives exceptional radiation purity in transmittance / absorbance measurement from 205 to 800 millimicrons; Direct reading meter — presents measurements in both transmittance and absorbance quickly and accurately; Single wide-range phototube — covers the entire range from 205 to 800 millimicrons, eliminates need to change even at wavelength extremes; Dual Hydrogen/Tungsten lamp source assembly — has high energy output, gives instant switching from one source to the other; Direct line-operated power supply — is stable, fully transistorized, eliminating batteries and drift problems; Low cost — brings the advantages of modern instrumentation to any laboratory with unmatched economy and superior performance.

The five basic functional units, in combination, provide the analyst with a fully integrated instrument for the rapid and precise analysis of any sample by absorption measurement.

For details see your Aloe Scientific representative or write Aloe Scientific, B Division of Brunswick, 1831 Olive Street, St. Louis 3, Mo.

Thomas announces the new . . .

Whirlpool Thermoelectric IMMERSION COOLER

FOR LABORATORY BATHS

- *produces sub-zero temperatures*
- *eliminates rigid coil connections*
- *compact, silent*

4049

COOLER, IMMERSION, THERMOELECTRIC, Whirlpool. A Peltier-principle thermal pump for lowering the temperature of laboratory baths. Capable of producing sub-zero temperatures (to −25°C from 25°C ambient) in bath volumes up to 4 liters in insulated vessels. Can be used in larger baths to provide cooling required to maintain control near ambient temperature. Operates on a 115-volt, 50 or 60 cycle a.c. line, on which the unit draws 165 watts. A slow-flowing source of cooling water at normal temperature is also required.

Cooling Unit. Made in the form of a thick nickel-plated copper blade, the cooling surface is 6 inches long × 2¾ wide × 1⅛ inches thick, providing an effective area of approximately 45 square inches when immersed to recommended depth. Three-pin receptacle for power input and tapped hole for horizontal attachment of 5½ × ⅜-inch diameter mounting rod are provided in polypropylene shank. Two ¼-inch o.d. tubulations emerge from top for connection of tubing for cooling water input and discharge. Thermoelectric modules within the outer shell are bonded to a cast bronze heat sink which is cooled by the passage of tap water. A thermal cut-off switch attached to the heat sink closes at 71°C if cooling water is inadvertently shut off *(see Power Supply)*.

Power Supply. Suitable for unattended, continuous operation to provide 3-volt, 25-ampere d.c. operating power. Contains transformer, two silicon diode rectifiers, choke for reducing output ripple, fuse, pilot lamp and thermal cut-off power switch. Heater in thermal cut-off switch is activated by closure of a bimetal switch attached to the heat sink inside the cooling unit. Although bimetal switch in cooling unit reopens when heat sink temperature drops to 55°C, power will not be restored until power supply switch is reset manually. Plug on d.c. power cable connects the power supply to cooling unit. A.c. input is supplied through a 3-wire cord, with 3-prong plug and adapter.

Cooling Rate. Non-linear; depends upon bath volume and temperature of heat sink coolant. In test with 3.5 liters of ethylene glycol, with coolant and initial bath temperature of 24°C, hourly temperatures were recorded as follows: 14, 4, −3, −8, −12, −14, −16, −17, −18, −19, −20, −21, −22, −23, −24 degrees Centigrade.

4049. THERMOELECTRIC COOLER, as above described, complete with d.c. power supply unit . . **250.00**

A.

FIESER and FIESER

ADVANCED ORGANIC CHEMISTRY

by Louis F. Fieser, Sheldon Emery Professor of Organic Chemistry, and Mary Fieser, Research Fellow in Chemistry, both of Harvard University

1961. 1,168 pages. $14.00

This textbook for upper division courses in organic chemistry presents the fundamental facts and theories of the chemistry of aliphatic, alicyclic, and aromatic compounds.

C.

FIESER and FIESER

STEROIDS

by Louis F. Fieser, Sheldon Emery Professor of Organic Chemistry, Harvard University, and Mary Fieser, Research Fellow in Chemistry, Harvard University

1959. 964 pages. $18.00

This text is a completely revised account of the entire field written from the perspective of modern theory.

E.

HEFTMANN

CHROMATOGRAPHY

Edited by Erich Heftmann, National Institutes of Health. Consulting Editors: Calvin A. VanderWerf and Harry H. Sisler

1961. 780 pages. $17.50

Written by outstanding international authorities, this book offers outstanding and complete coverage of a basic analytical tool.

B.

FIESER and FIESER

TOPICS IN ORGANIC CHEMISTRY

by Louis F. Fieser and Mary Fieser, both of Harvard University

1963. 680 pages. $10.00

This new textbook contains the most up-to-date coverage of an important group of nine special topics, plus a review of the latest advances in general organic chemistry. It will serve as a useful text for upper division courses in organic chemistry.

D.

FIESER and FIESER

ORGANIC CHEMISTRY, Third Edition

by Louis F. Fieser and Mary Fieser, both of Harvard University

1956. 1,118 pages. $10.00

This famous international textbook develops in orderly sequence the principles and concepts of modern organic chemistry and the applications of the fundamental science to technology and to biochemistry and medicine. It has been widely adopted for use as a basic text in undergraduate general organic chemistry courses.

Topics in . . .

Chemical Instrumentation

. . . a Chem Ed feature

Edited by **S. Z. LEWIN**, New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

X. Emission Spectroscopy. Part One

Stephen E. Wiberley *and* **Herbert H. Richtol**, *Department of Chemistry Rensselaer Polytechnic Institute, Troy, New York*

S. E. Wiberley is Associate Dean of the Graduate School at R.P.I. He was educated at Williams College (B.A. 1941) and R.P.I. (M.S. 1948; Ph.D. 1950). He teaches analytical chemistry and is author of three textbooks and approximately 50 papers in such research areas as spectroscopy and instrumental analysis.

Herbert H. Richtol is Assistant Professor of Analytical Chemistry at R.P.I. He was educated at St. Lawrence University (B.S. 1954), and New York University (Ph.D. 1961). He teaches analytical chemistry and has research interests in the fields of spectroscopy, luminescence and energy transfer processes.

The field of emission spectroscopy is a very broad one and for adequate coverage would require an excessively long article. This review will attempt to emphasize a few of the highlights and recent developments in this field. Flame photometry will not be included since a previous article in this series dealt exclusively with this subject.

General Principles

Emission spectra can arise from excited atoms or molecules with atoms yielding line spectra and molecules band spectra on the photographic plate. Under high resolution the band spectrum of a simple molecule consists of many fine lines closely grouped together so the differences between some band spectra and line spectra are not as pronounced as a casual inspection of the photographic plate would first indicate. The instrumentation for emission spectroscopy will be discussed in terms of line or atomic spectra because the major use lies in this area rather than in the area of band spectra. However, the same instrumentation can also produce excellent band spectra as well.

An electron in the ground state may be excited to a higher energy level if suitable energy can be imparted to the electron by a flame, arc or spark. On returing from this higher energy level to a lower level, radiation is emitted with a characteristic wavelength such that $\Delta E = hc/\lambda$ where ΔE is the energy in ergs, h is Planck's constant, approximately 6.6×10^{-27} erg-sec, c is the speed of light, approximately 3×10^{-10} cm/sec, and λ is the wavelength in centimeters. In emission spectroscopy the wavelengths are reported in angstrom units with the angstrom being originally defined as 10^{-10} m in terms of the standard meter bar. Because the meter bar was not an adequate standard for wavelength measurements, the angstrom was redefined as a unit of length equal to 1/6438.4696 of the wavelength of the red line of cadmium. This value was almost but not exactly 10^{-10} m. Most recently (*1*) the meter has been defined as 1,650,763.73 wavelengths (in vacuum) of the orange-red line of Kr^{86}. With this new definition the angstrom is again exactly 10^{-10} m or 10^{-8} cm.

Since only certain discrete energy transitions are allowed, the radiation is quantized and the wavelengths of the emitted radiation are characteristic of the atom producing the radiation. By measuring these wavelengths or by comparison with spectra of known elements the atom or element can be identified *qualitatively*. The intensity of a given emission line of an element is a function of the probability of the electronic transition taking place and the number of atoms of the element concerned. By measuring the line intensity either photographically or with a phomultiplier tube, *quantitative* analysis can be carried out.

Detection of the Elements

Of the total of over 100 elements which have been discovered, including those made artificially in trace amounts, some 87 have been investigated spectrographically. However, only 72 elements can be readily detected and these elements are shown in Figure 1. De Gramont studied the emission lines that persisted as the concentration of the element was decreased. In 1920 he published (*2*) a table of persistent lines also known as sensitive or principle lines (raies ultimes or letzten linien). In this table he indicated the raies sensibles and raies ultimes as the persistent lines in the visible and ultraviolet regions of the spectrum, respectively. The term raies ultimes was later applied by Meggers (*3*) to include both spectral regions and is used in this sense by spectrographers today.

Using a DC open arc as a source of excitation and a selected RU line in the range of 2000–4600 Å elements detectable in the <1–10 ppm limit include Ag, Al, Au, B, Ba, Be, Bi, Ca, Cr, Cu, Fe, Ga, Ge, In, Mg, Mn, Nb, Pd, Pt, Rh, Si, Ti, and all of the rare earths except Nd, Pr, Sm, and Tb. Elements detectable in > 10–100 ppm limit include As, Cd, Co, Ga, Ni, Pb, Sb, Sn, Sr, Tl, V, Zn, and Zr and > 100–1000 limit include Hg, Se, Te, Th, and U (*4*). With the Stallwood Jet, which controls the direct current arc by surrounding a small diameter electrode vertically with a stream of a mixture of 70 parts argon to 30 parts oxygen, the sensitivity is improved by a factor of 2 or more for most elements. In addition, quantitative accuracy is improved (*5*).

Although not shown in Figure 1 such nonmetallic elements as C, S, Se, P, F, Cl, Br, and I and the gaseous elements such as H_2, O_2, and N_2 can be determined spectrographically. The characteristic spectral lines of the non-metallic elements have excitation potentials two to four times greater than those of the metallic elements with the principal lines being below 2000 Å so either a vacuum or an inert atmosphere must be used in the spectrographic arrangement. Fluorine, chlorine, and bromine combined with an alkaline earth can be analyzed with a DC arc by measurement of the molecular bandhead. For example, calcium fluoride has a strong bandhead at 5291 Å enabling measurement of fluorine in the 50 ppm range. Carbon can be analyzed from bandheads at 3590, 3883, and 4216 Å of cyanogen formed from the combination of nitrogen in the air with carbon in the arc.

In the study of detection limits the purity of the electrodes is an important factor. High purity graphite electrodes are sold with an analysis report containing an estimation of the impurities present. Until recently most graphite electrodes contained boron and vanadium as impurities as well as aluminum, copper, silicon, iron, and magnesium. Selected graphite can be obtained free of one or more of these elements today and is available in a wide variety of preformed electrode shapes from several manufacturers.

THIN-LAYER ELECTROPHORESIS

Two-dimensional separation of 5 amino acids on silica gel, first by electrophoresis, then by chromatography: 1. Arginine 2. Glutamic acid 3. Valine 4. Histidine 5. Leucine

Thin-layer electrophoresis is a new analytical technique which combines with thin-layer chromatography to give you separations that you can't get by using both techniques separately. Scientists experimenting with TLE report instances of unexpectedly high mobilities as well as greater speed, sharper resolution, increased sensitivity, wider range of sample size, better reproducibility, and other advantages. □ RSCo is the only domestic company which makes complete equipment for TLE, and our dealers now have it in stock. If you already use RSCo electrophoresis or other flatbed equipment, you can adapt it to TLE with our assembly at a cost of only $162.

Want more information? Write for our free RSCo Review, Vol. 5, No. 5.

Chemical Instrumentation

Qualitative analysis on a given sample is often carried out by obtaining on the same film the spectrum of the unknown sample and a spectrum of a standard powder containing a large number of elements. Often an iron arc spectrum is also included on the film as an additional reference. Two standard powders available commercially are RU powder and Qual Mix Ru powder consists of a base mixture of calcium oxide, magnesium oxide and zinc oxide to which 47 other elements have been added in such amounts that only a few of the persistent lines appear for each element. Qual Mix is a similar powder containing 43 of the common elements. In many laboratories a standard film, with an iron arc spectrum of half-length lines and the most persistent lines of the elements in full length marked with the element symbol and the wavelength, is kept in a simple comparator or a comparator-densitometer. The film containing the spectrum of the unknown sample is then placed in the comparator and aligned so that the iron arc lines match those of the standard film. The elements in the unknown sample can then be readily identified by comparison with the standard film. Standard films are commercially available for most photographic instruments or can be made to order. A short segment of such a film is shown in Figure 2.

Figure 2. Representative segment of standard comparator film.

Quantitative Analysis

In emission spectroscopy quantitative analysis is usually carried out either for semiquantitative results or for quantitative results with as high a precision and accuracy as possible. In both instances one of the main obstacles to be overcome involves matrix effects. The intensity of

Four reasons why the new H6 saves time and money

- A new 100 scale division micrometer permits direct reading to .1 mg without estimation.
- The 1200 mg optical range is the largest available in any analytical balance.
- Only 2 knobs control all weight combinations up to the full 160 g capacity.
- A patented damping system rapidly brings the balance into equilibrium.

This new Macro-Analytical Balance features a 1200 mg optical range, ± 0.05 mg precision and direct reading to .1 mg. It can be operated by unskilled laboratory personnel, liberating skilled specialists for other work; it reduces the sources of error in analytical work; and it makes weighings fast!

If you would like to try this new balance, or want more detailed information, contact your Mettler dealer now, he will be glad to arrange a demonstration or trial.

Picker quality nuclear training instruments at budget outlay

PICKER NUCLEAR TRAINING INSTRUMENTS permit scheduling full laboratory courses in radioisotope techniques.

These transistorized instruments are remarkably compact (as you can see above). They are good-looking, rugged, easy to understand, and simple to use. They have the versatility and capacity not only for basic nuclear training, but for handling advanced techniques like pulse height anaylsis and rate function studies.

Their cost falls well within the reach of modest equipment budgets, such as those supported by A.E.C. grants-in-aid in pursuance of its Nuclear Education Program.* For details, please call any local Picker office (see 'phone book) or write Picker X-Ray Corporation, 25 South Broadway, White Plains, New York.

** The Picker Nuclear Division is prepared to help interested institutions in drawing up training programs in the use of nuclear techniques in biology, chemistry, medicine, agriculture, physics, and other fields.*

Picker nuclear

Standing behind every Picker instrument is a local member of the Picker X-Ray national sales and service network.
He's there to protect your investment.
Because of him the user of a Picker instrument is never left stranded.

the emitted spectral line of an element is influenced by the matrix, i.e., the other elements constituting the bulk of the sample. For example, in the analysis of a 24S aluminum alloy containing approximately 5% copper, 1.5% magnesium, and smaller amounts of iron, silicon and manganese, standard samples of 24S alloys analyzed by wet chemical methods must be available if an accuracy of 5% is required. Other alloys such as types 2S and 3S containing only 0.10% copper would not be suitable as standards for a 24S alloy. The spectrographer, therefore, requires a large number of standard samples of known composition. It should be pointed out that the ultimate absolute accuracy of any quantitative spectrographic analysis is dependent upon the accuracy of the wet chemical analysis. Thus, in this era of complex chemical instrumentation, the importance of wet chemical analysis should not be overlooked.

In quantitative analysis many variables come into play. The source of excitation, usually a high voltage spark, must be carefully controlled. In the case of solid samples such as metal discs the surface must be carefully machined and the distance of the electrode to the surface of the sample is important. Proper focus of the emitted radiation on the slit of the spectrograph must be made for each exposure. Another important variable is involved in the photographic process. It is necessary to relate the blackening of the photographic plate (i.e., the line density) to the intensity of the light emitted at the source. Since there is no exact mathematical equation relating image density and the intensity of light producing the image, it is necessary to express this relationship graphically and even then the intensities obtained from the graph are relative rather than absolute values. Each batch of photographic emulsions must be calibrated by one of several alternate methods (*6,7*). One method of controlling many of the variables is to use the well established internal standard technique. Rather than measuring just the density of the line of the element to be determined and relating this to the concentration of the element, a second line of an element whose concentration in the matrix is fixed, i.e., an aluminum line in an aluminum sample or an iron line in a steel sample, is chosen as an internal standard and the intensities of both lines are measured. The logarithm of the intensity ratio is then plotted against the logarithm of concentrations as shown in Figure 3 to obtain a standard calibration curve. Thus, variation in the sparking, or developing procedure could change the absolute intensity of each line but not the intensity ratio.

The microphotometer or densitometer is used to measure the blackening of the photographic emulsion. The blackening is related to the emitted intensity and thus to the concentration of an element. The measurements are made in terms of the

Figure 3. Typical calibration curve for quantitative analysis.

galvanometer or recorder pen deflection, the clear emulsion usually rated as 100 and complete opacity rated as 0.

The essential parts of a photoelectric microphotometer include a source of light (tungsten lamp), a slit to select the desired portion of the emulsion, a holder for the plate, a phototube, and a circuit and scale for reading the photocurrent. Other features include a magnifying or projection system for viewing a reasonable portion of the spectrum, a wavelength scale for locating the lines, and a means of moving the plate horizontally (scanning) across the slit field to obtain the scale reading, and vertically (racking) to move from one spectrum to another. In all instruments available commercially, the maximum excursion of the galvanometer or pen is read as the line is scanned. A typical commercial densitometer is shown in Figure 4.

Figure 4. The Jaco densitometer.
(Courtesy Jarrell-Ash Company)

If a microphotometer is not available, rough quantitative results can be obtained with the log sector method. A log sector is a rotating sector placed in front of the slit. It is shaped in such a manner that the slit is illuminated logarithmically along its length as the sector rotates at high speed. The line shapes produced are shown in Figure 5. At some point along the line image, the illumination will be below the threshold intensity and the line will fade out. Hence, the length of the line image gives a measure of the source intensity at that wavelength.

no vapor condensation in these new LaPine VACUUM MASTER (TM) high vacuum pumps . . . made by Leybold!

Prolonged pumping time, limited ultimate vacuum obtainable and annoying oil contamination are but a few of the frustrations one is apt to meet when using ordinary high vacuum pumps. The villain committing these dastardly deeds is Vapor Condensation! The excessively high compression ratios high vacuum pumps must achieve in order to discharge gases from the vacuum system—often as high as 760:1—compress vapor particles so greatly that they condense to form droplets. As a result, the exhaust valve is not forced open by pump pressure and exhausting does not take place.

In LaPINE Vacuum Master High Vacuum Pumps, fresh air—gas ballast—drawn from the outside, solves the problem. Excess pressure in the pump required to open the exhaust valve is produced before water particles can condense. Vacuum Master pumps may be operated first with the gas ballast valve open to remove vapor—then run with the valve closed to obtain desired higher vacuum.

CHOOSE THE LaPINE Vacuum Master PUMP TO MEET YOUR EXACT REQUIREMENTS . . . Four are available: Single-Stage, models 2S and 6S; Two-Stage, models 2D and 6D. All are manufactured by E. LEYBOLD's Nachfolger of West Germany, incorporate the most recent developments in pump design, and carry forward the 100-year-old LEYBOLD TRADITION of precision-manufacture, fine performance and absolute reliability.

Some of their superior features: Low ultimate pressure . . . Low noise level . . . High water vapor tolerance . . . Gas ballast operation at the twist of a knob . . . Visible oil level . . . No oil foaming . . . and Connections in seconds with small-flange fittings. Write today for your copy of the complete "LaPINE Vacuum Master High Vacuum Pumps" bulletin.

The emulsion calibration and analytical curves are prepared in a manner similar to that employed when line densities are measured except the values of the lengths of the lines are used in place of the logarithms of the deflections obtained on the densitometer. The internal standard technique is also involved. Ratios of line heights of the element being determined to that of an internal standard element are used rather than absolute line heights.

Figure 5. Typical spectra obtained on an aluminum alloy with the log sector method. The lines of selected elements are indicated.

Excitation Sources

The function of an excitation unit is to introduce the sample into the discharge in a vaporized form and to excite electrons in the vaporized atoms to higher energy levels. With the excited atoms emitting characteristic frequencies giving rise to lines on the film or the photographic plate, it is a reasonable assumption that the intensity of an elemental line in a mixture as viewed on the photographic plate is directly proportional to the number of atoms in the sample. Unfortunately this assumption may seem incorrect because of differing volatilities of the components of the mixture. As previously mentioned a properly chosen internal standard with vaporization properties similar to the unknown element is frequently used in quantitative work. Under these conditions the intensity ratio of unknown to standard will be proportional to the unknown concentration.

The DC arc is a common method of introducing the sample into the discharge. Vaporization occurs as a result of the discharge when the arc is struck and heating caused by the passage of current. The DC arc can be used in semiquantitative work with the sample burned to completion at temperatures ranging from 4000 to 8000°C.

The necessary components for a DC arc are a direct current power supply, a variable resistor and a discharge gap. The arc is a very sensitive method of excitation, because so much of the sample is consumed and excited. Figure 6 shows a circuit of the DC arc in the Baird atomic spectrographic source unit. The rectifier produces a DC current at the gap, and a series of fixed resistance steps and a rheostat allow the selection of any current from 1 to 30 amp. The open circuit voltage available to maintain and stabilize the arc is over 300 v on any step. Most of the elements can be determined by the DC arc with a good line to background ratio.

An attachment frequently used with the DC arc to enhance sensitivity is the Stallwood Jet shown in Figure 7. In the Stallwood Jet of Spex Industries Inc., gas is forced into a swirl chamber and then upward through an orifice surrounding the sample electrode. As the electrode burns, it may be advanced with respect to the curtain of gas. Instead of the gas entering the open atmosphere after leaving the orifice, it enters a quartz enclosure where, by building up a slight positive pressure, air is excluded. The most typical gas used is an argon-oxygen mixture.

FRACTION COLLECTORS
for every program... for every budget!

CONTINUOUS . . .
for long-term or overnight use.
• 240 test tubes, 18 x 150 mm
• Four rows of 60 each.
• Turntable, 24" diameter.
• Time drop and volume collection.

REFRIGERATED . . .
the mobile coldroom, refrigerated from column to collecting tubes.
• Fractions in the turntable temperature-controlled.
• Fraction collectors removable for all-purpose cold-room work.
• Mobile—on casters.

25 different models, including SECTIONAL (for processing during fraction collecting)

For complete description of all Fraction Collectors write for Bulletin JC3-4000

The VARIGRAD
VARIABLE GRADIENT MIXER FOR CHROMATOGRAPHY
A unique apparatus FOR PRODUCING PRECISELY-CONTROLLED AND REPRODUCIBLE GRADIENTS
Developed at the National Institutes of Health

• Makes small changes in specific portions of an elution gradient to improve resolution in certain regions to chromatograms.
• Presents gradient data for duplication in any laboratory.
• Single apparatus can be used to supply identical gradients simultaneously to several columns.
• Any number of independent gradients of different molecular or ionic species can be produced simultaneously.

Send for Bulletin JC3-4000 for complete information

New Torsion 1,000 gram balance speeds laboratory work

Only Torbal 1/10 gram PL-1 offers all these features

- *Fast, accurate readings optically projected to 1/10 gram*
- *No-knife edge construction eliminates friction and wear*
- *Greater taring range*
- *Remains unaffected by out-of-level conditions*
- *Oil dampened to speed weighings*

Price only $525.

To give you more convenient, accurate readings, Torsion has designed the PL-1 with a fine-reading vernier to 1/10 gram and a capacity of 1 kilogram. The balance has an optical range of −10 grams to +110 grams.

The heart of the mechanism in the new PL-1 is the Torsion no-knife edge construction. This eliminates friction and wear, insures lifetime accuracy and speeds weighing. The balance will operate accurately even in severely corrosive or dust-laden atmospheres.

Taring through a 125 gram range is accomplished with a built-in knob on the side of the balance. By using the second pan the balance can be made to tare up to 325 grams. Torsion's optical projection Model PL-1 offers a sharp image with a high degree of illumination for easy reading and an oil damper to speed up weighing.

Enhanced sensitivity is achieved with the Stallwood Jet for two reasons. One is that cyanogen bands are eliminated, and even though raies ultimes depend on the gases used, elements hidden in the cyanogen bands are more easily detected. The sensitivity of molybdenum, the rare earths and iron are considerably enhanced in nitrogen free atmospheres. The second reason for improved sensitivity is that the excitation efficiency of a sample can be markedly increased if it is forced to burn slowly. A volatile material such as arsenic or selenium is detected with marked sensitivity when placed in a deep cratered electrode and burned slowly when cooled with the Stallwood Jet gas stream.

The AC arc is generally more sensitive than the DC arc and can detect elements below the limit of detection of a spark. Although the AC arc lacks the very high analytical precision of the spark, it is more sensitive and is used extensively for trace element determinations. In the Baird-Atomic AC arc shown in Figure 6, the transformer is equipped with two secondary windings to provide either 5 amp at 2750 v (open circuit), or 2.5 amp at 5500 v (open circuit). The gap breaks down as the voltage reaches its peak in each half cycle, and the voltage drops rapidly to 30–80 v and an arc-like discharge occurs until the voltage starts to reverse. The arc is now terminated and reignited on the next half cycle. The arc is stabilized by a ballast resistor and the transformer and the maximum current is limited to 50 amp. The reignition each half cycle on a random part of the material provides a good sampling technique.

The AC spark is the preferred source whenever high precision rather than extreme sensitivity is required. The determination of per cent concentrations of alloying elements in metals is a typical area where the spark source finds extensive applications. The variety of spark sources available all have basically the same secondary circuit consisting of a high voltage capacitor, an inductance, a resistance, and the gap. The various sources mainly differ in the mechanism used to trigger the breakdown of the analytical gap. The oscillatory gap discharge is a damped wave train, with the majority of the power appearing in the first wave. Exceptional precision is obtained because the spark circuit provides a series of discrete and identical breakdowns of the analytical gap. The sample is subjected to a high degree of excitation without excessive heat. The introduction of sample

Wavelength ranges covered by Perkin-Elmer low-cost infrared spectrophotometers.

performance-proved instruments for INFRARED SPECTROSCOPY

KEEP YOUR LAB AHEAD IN INFRARED WITH THESE LOW-COST SPECTROPHOTOMETERS

Each member of the Perkin-Elmer low-cost infrared spectrophotometer line does so many jobs so quickly and so well—in both large and small laboratories—it frequently saves its cost within a short period. Simple in design, all Perkin-Elmer low-cost spectrophotometers are easy to operate, rugged and reliable. They are capable of solving a high percentage of the problems encountered in chemical research and development, process and quality control.

Low-cost infrared spectrophotometers can be ordered from Perkin-Elmer in any of four linear wavelength spectral ranges: the NaCl prism Model 137B from 2.5 μ to 15 μ; the KBr prism Model 137B from 12.5 μ to 25 μ; the high-resolution grating Model 137G, with two ranges covering .83 μ to 7.5 μ; and the double-grating Model 237, operating also in two ranges, from 2.5 to 7.7 μ and from 5.0 to 16 μ. Both 137G and 237 are available also in linear wave-number modes. For descriptive literature, including sample spectra, write to Instrument Division, Perkin-Elmer Corporation, 870 Main Avenue, Norwalk, Conn.

Digitized by Arya Samaj Foundation Chennai and eGangotri

Some people need to stretch the spectrum to 45 feet...

This is why Beckman offers you the broadest line of infrared spectrophotometers.

To serve your specific need.

Whether it's simple or complex. Whether it demands routine repetition or extreme versatility.

Whatever it is, you will find the appropriate spectrophotometer in this distinguished line.

About the IR-4

This was the first double-beam instrument to incorporate double-monochromator design with high energy, high resolution, and low stray light.

And now, it's also well known for its extreme versatility and success in highly specialized applications. Like external source studies. Reflectance studies. And external detector monitoring.

You also can extend the IR-4 range through the visible and UV regions in just minutes for source and detector studies. And all of this doesn't hinder its ability to perform usual analyses.

About the IR-5A

There are two different versions of this low cost laboratory workhorse.

The standard NaCl Model offers a range of 2-16μ. And the CsBr IR-5A covers the 11-35μ region.

Both models have a 3 and 15 minute scan, single and double beam operation, and the Beckman quality of design and construction.

For routine analysis, the IR-5A is unmatched.

About the IR-7

This is an excellent prism grating instrument with high resolution for exacting research studies.

The IR-7 also offers more versatility in infrared spectroscopy than any other spectrophotometer in its price class. Every parameter is fully adjustable.

In double beam operation, you can take advantage of the time proven optical null system for your most precise differential work. In single beam, you get true direct energy measurements.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

...some people don't

Like the IR-4, the IR-7 can be modified to meet every infrared analytical need.

About the IR-8

This instrument provides the highest resolution and the fastest scanning in the low cost field. Available in linear wavelength or linear cm^{-1}.

The entire range of 2.5 to 16μ can be continuously scanned on a single chart in either 8½ or 25 minutes. That means you can leave the IR-8 completely unattended throughout its full run.

The IR-8's dependability and reliability is assured because it is patterned after the time proven IR-5A. Its high resolution is due to a filter-grating monochromator using four long pass interference filters and two diffraction gratings.

About the IR-9

Let's face it ! ! ! This is the most advanced infrared spectrophotometer in the world. It has the broadest frequency range available (4000-400 cm^{-1}) in a prism grating double monochromator. The highest frequency accuracy available. Continuous spectra with no order breaks or filter spikes. And resolution second to none.

You can stretch the spectrum to 45 feet on a continuous chart or have it on conventional sized chart paper.

With modification and additional gratings, you can extend the IR-9's range to 33 cm^{-1}.

About all of these

For information on these instruments and our complete line of accessories and attachments, call your Beckman Sales Engineer or write for Data File LIR-36-164.

into the gap by the spark is primarily by ion bombardment of the cathode in the first microsecond when the potential drop across the electrodes is quite high. In the Baird AC spark unit shown in Figure 6, the transformer secondary output is about 25,000 v at 60 cps. During each half cycle, the transformer charges a condenser bank to a sufficiently high voltage to break down the auxiliary gaps and the condensers discharge through these gaps. The spark is quenched by an air blast blowing across the auxiliary gap, and the condensers charge again for another breakdown.

Other companies producing somewhat similar excitation units are Applied Research Laboratories, Jarrell-Ash Company and National Spectrographic Laboratories.

A new excitation source recently developed by the Jarrell-Ash Company is the laser microprobe. A wide variety of materials may be directly analyzed by this source without extensive sample preparation. A schematic diagram of the laser microprobe is shown in Figure 8. The laser beam is concentrated into the sample by a microscope. The intense heat vaporizes the sample which short circuits an auxiliary electrical gap positioned between the sample and microscopic objective. Spectral emission takes place during the short circuit. This method permits a spectrum of the sample to be recorded on a one-shot process.

"Emission Spectroscopy," Part Two, will be concluded in the January 1964 issue. That installment will cover monochromators and typical commercial instruments.

Figure 8. Simplified drawing of the Jarrell-Ash laser microprobe.

NOTE

The Editors will be pleased to discuss possible contributions to this series with potential authors who feel they have a paper of this type on an appropriate theme. A prospective author is asked to check annual indexes to note topics already treated and to be familiar with the general style and format of the papers. Inquiries should be addressed either to Professor S. Z. Lewin, New York University, New York 3, N.Y. or to The Editor, W. F. Kieffer, Dept. of Chemistry, Room 6-123, Massachusetts Institute of Technology, Cambridge 39, Mass.

digital-type reading

Another first from Sartorius.

Sartorius pioneered in the introduction of analytical balances with a 1000 mg optical range reading direct to 0.1 mg (without interpolation). Now, while most competitive instruments still offer shorter, less practical, optical ranges, Sartorius is first to introduce a new projection scale on which each division is individually numbered. And, this scale is available on models with various sensitivities including a semi-micro version (reading direct to 0.01 mg).

The Digital Read-Out was achieved through an increase in magnification made possible by Sartorius' longer light path—because the scale is located in the base of the housing.

The new image is physically much larger and brighter than scales on other balances, and the higher magnification has also improved reproducibility.

In every respect, weighings are simpler and faster. Reading errors are virtually impossible. Before you buy, compare the Sartorius Projection Scale and the Sartorius Balance to any other model available. You cannot appreciate the difference until you see it. Prices begin at just $725.

Today, Sartorius is first in balance design.

FILTRATION CHART

for use in chemical analysis

relative retention values

OF S&S ANALYTICAL FILTER PAPERS

Our laboratory pioneered new methods for the quantitative evaluation of filter papers which have proved of considerable help to the chemist in the standardization of their speed and retention ranges.

This retention method, employing a finely divided dispersion, assigns numerical test group values to S & S filter papers – for equal precision with very fast, loose textured grades and sheets of greatest density.

The wide range of this novel retention scale, and the diversity of S & S filter papers, are represented graphically on the sedimentation cylinder. The graphic representation is illustrative of the general range of retention of S&S Analytical Filter Papers. For additional copies of the S&S Filtration Chart, address Dept. JCE-312.

ACT-O-MATIC™

DUAL-POSITION PROJECTOR

SETS THE STAGE INSTANTLY for vertical or horizontal science projection

Compare these features

- self-contained unit, needs no adapters or rebuilding for dual projection
- colorful "live action" projection always in sharpest focus
- continuous sequence from vertical to horizontal operation and back again
- constant, short focal length keeps instructor up front of the class
- exclusive triple condenser system for high light intensity and even illumination
- exceptional visibility for as many as 300 students

Act-O-Matic gives every student a front row seat and keeps the instructor at the head of his class for all science demonstrations. "Live action" projections, instantly transferred from vertical to horizontal positions and back to vertical, maintain a lively unbroken sequence to hold every student's interest and make every lecture a simple project for the instructor. **Only** Act-O-Matic can give you a completely integrated projection system to meet all of the "TOPS" requirements. **Only** Act-O-Matic can assure you of the full power and versatility to do the whole science demonstration job ...without costly adjustments or makeshift adaptations. **Only** Act-O-Matic provides the most complete line of accessories and devices designed to do a full science projection series.

WRITE OR CALL TODAY FOR BULLETIN AOM62

WORLD FAMOUS DESIGNERS AND MANUFACTURERS OF EDUCATIONAL SCIENCE FURNITURE

vertical

Demonstrations projected involving liquids, heating and cooling, gravitation, gas generation, and devices such as electrolysis cells, flasks, electroscopes and various measuring instruments.

horizontal

Projects transparencies up to 5" x 5", petri dishes, culture dishes and watch glasses. Also action notes and diagrams as rapidly as they are written or set on the projection stage in prepared form.

3. CHEMICAL REACTIONS OF WATER *(continued)*

Dem. 107—Heat of Hydration of H_2SO_4

(Experiment developed by Lilias Brescia, LeRoy Hornbeck, Fred Rolf.)

To show: Heat is evolved when conc. H_2SO_4 is mixed with water. ($H_2SO_4 + H_2O \rightarrow H_2SO_4.H_2O$, the monohydrate forms).

Method 1.

Materials: M°, conc. H_2SO_4, dropper.

Procedure: Project M° with box two-thirds full of water. Suddenly squirt a ml or more of conc. H_2SO_4 into the water, taking care not to squirt it against the plastic (would damage it).

Observation: There is rapid, dramatic rise in temperature.

Notes: *1.* "The water should be in before you add the H_2SO_4; or else you might not feel too well; you might not even live to tell."

2. "If you're doin' what you oughter add the acid to the water; May your rest be long and placid, adding water to the acid."

Method 2.

Materials: Ether, iodine, H-3, conc. H_2SO_4, 6 mm tubing 6-in. long, cork stopper, epoxy cement.

Preparation: Seal one end of the tubing. Quarter fill it with ether containing enough iodine to project clear brown. Push in the cork and fill the upper $^1/_4$-in. of the 6 mm tube with epoxy-cement. (*Note:* do not seal at both ends, this cementing technique is much safer and simpler.)

Proceedings: Place a culture tube in H-3 and project. One-quarter fill it with conc. H_2SO_4. Cautiously (CARE) pour an equal volume of water so it rests on the acid. Now insert the ether-iodine rod and (CARE) stir.

Observations: The violent evolution of heat from the hydration of the acid is sufficient to cause the ether to boil vigorously.

Notes: *1.* This is safer than Tested Demonstration No. 4-11, where an open tube is used and the boiling ether is ignited. The flame would not be visible on the projector.

2. Lay the ether-iodine stirring rod away for reuse, it keeps indefinitely.

3. Also (*a*) methanol with methyl red, or (*b*) carbon disulfide with iodine can be used.

B. ACIDS, BASES

1. PREPARATION OF ACIDS AND BASES

Dem. 108—Acid Anhydrides

To show: The preparation of acids from acid anhydrides.

Materials: Phenolphthalein indicator, H-1 with a straight not curved-up delivery tube, dry ice, Cu wire, conc. HNO_3, NaCl, conc. H_2SO_4, $NaHSO_3$, dil. H_2SO_4, P_2O_5, five 4-in. culture tubes, dil. NaOH-aq.

Procedure: To 100 ml water add a few drops of phenolphthalein plus a drop of very dilute NaOH to make the solution distinctly red. Fill the culture tubes half-full of this solution. Set one in H-1 and project. (*a*) *Carbonic acid.* Drop a lump of dry ice into the red solution. (*b*) *Nitric acid.* To $^1/_5$th a tube of conc. HNO_3 in the generator H-1 add a Cu wire. Bubble the off-gas into the red solution. (*c*) *Hydrochloric acid.* Ditto, with NaCl + conc. H_2SO_4. (*d*) *Sulfurous acid.* Ditto, with $NaHSO_3$ + dil. H_2SO_4. (*e*) *Ortho-phosphoric acid.* Add a pinch of solid P_2O_5 to the red solution.

Observations: Each solution turns colorless as the acid anhydride dissolves in the water to form an acid, viz. H_2CO_3, HNO_3 + NO, HCl, H_2SO_3, and H_3PO_4.

Note: It is also instructive to start with sulfur and burn it in air, then dissolve the remaining material (enough SO_2 remains on the sulfur) in the phenolphthalein solution. Ditto, red phosphorus.

Dem. 109—Basic Anhydrides

To show: The formation of bases from basic anhydrides.

Materials: CaO, old lump of Na, phenolphthalein indicator solution, cell C-2.

Procedure: Two-thirds fill the chambers of C-2 with water and add a drop of very dilute indicator to each. (*a*) Add a pinch of CaO to one. (*b*) Scrape off *only* the white coating on a lump of sodium, explaining to the class that it is a mixture of sodium oxide and peroxide. Be sure not to have any sodium in the scrapings. Drop into the other chamber.

Observations: Both form hydroxides ($Ca(OH)_2$ and NaOH) and turn the indicator red.

Dem. 110—Formation of an Hydroxide by Electrolysis

To show: The formation of potassium hydroxide by the electrolysis of KI-aq.

Materials: E-1 with U-tube and short Pt electrodes, KI-aq. containing a drop of phenolphthalein indicator.

Procedure: Fill the U-tube with the solution; insert in E-1, and insert the Pt electrodes. Project. Switch on the current. After a few minutes, reverse the current.

Observations: (*a*) Brown iodine forms at the positive pole, and sinks in a streamer into one limb. KOH forms at the other pole and turns the indicator red. (*b*) Reversing the current reverses the effect.

Dem. 111—Electrolytic Writing

(Experiment developed by Edwin H. Cooper.)

To show: Formation of a base during electrolysis.

Materials: 5 × 5-in. Al foil, 5 × 5-in. blotter or heavy filter paper, 5 × 5-in. glass plate; KI, gelatin, soluble starch, ethyl alcohol, phenolphthalein, 45-v source (e.g., Burgess 230 Nx 45 v), 6 mm tubing, No. 18 Cu wire, insulated Cu bell wire.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Preparation: (*a*) *"Liquid write"*. Make starch solution from 0.8 g starch made into paste and added to 20 ml boiling water. Make indicator solution from 0.8 g phenolphthalein + 10 ml water + 10 ml ethyl alcohol. To 80 ml saturated KI-aq. add the starch and indicator solutions (add more alcohol if the solution remains cloudy). Now stir in, gradually, 12 g gelatin, and warm the solution until the liquid is a uniform tannish color. Cool. (*b*) *Writing styluses*. Jamb a No. 18 Cu wire through a 6 mm tubing 15 cms long. Solder one end to thinner insulated wire (bell wire). Make a second stylus. Connect the two to the 45-v battery. (*c*) *Writing surface*. Cut a $4^1/_2 \times 4^1/_2$-in. square out of the Al foil so as to make a 5 × 5-in. frame $^1/_2$-in. wide. Moisten the paper and place it on the glass, then press the Al foil frame snugly upon the paper.

Procedure: Spread two or three drops of "liquid write" over the blotting paper on the plate, making sure the solution touches the edge of the Al strip. Touching one stylus to the Al frame, "write" in the solution with the other stylus.

Observations: The negative stylus will write red ($2H_2O + 2e^- \rightarrow H_2 + 2OH^-$), whereas the positive stylus will write darkly (first the iodine is liberated, $2I^- \rightarrow I_2 + 2e^-$, then the iodine reacts with the starch to give a blue-brown color). The moist paper is translucent.

Notes: *1.* To erase, rub the finger over the solution, which is then ready for more writing.

2. Although this will work without the Al foil frame, by placing both styluses on the "liquid write," the immobile stylus leaves an undesirable mark. (Cooper)

Reference: Oxidation and Reduction of Ions at Electrodes, GILETTE, COL. E. C., JR. *J. Chem. Educ.*, **34**, A209 (1957).

2. SOLUBILITY OF ACIDS AND BASES

Dem. 112—Solubility of HCl in Water

(*Experiment developed by Alphonse Palermo.*)

To show: The extremely rapid dissolving of HCl gas in water.

Materials: Four-inch culture tube, a 3 × 1 × 1-in. clear plastic trough, conc. HCl, conc. H_2SO_4, Ehler's green food color or any acid-base indicator.

Procedure: Project trough two-thirds full of water tinted green. Put a dropperful of conc. H_2SO_4 in the culture tube. Carefully run a dropperful of conc. HCl upon this. *At once* invert in the trough of water. (Wash acid off of thumb!)

Observation: After a five-second delay the tube fills with HCl gas, and water rises to nearly fill the tube. The food coloring turns yellow.

Reference: ARENSON, S. B., for CHANDLER, E. E., **17**, 513 (140).

Dem. 113—The Ammonia Fountain

To show: The rapid dissolving of ammonia in water, to give a fountain effect.

Materials: Phenolphthalein indicator, conc. NH_4OH, test tube with one-hole stopper carrying a 5-in. length of 6 mm tubing, burner, 3 × 1 × 1-in. clear plastic trough, square 1-oz dropper bottle, the upper third of its rubber bulb cut off diagonally.

Procedure: See Diagram 113. Project with the trough nearly full of water containing a few drops of indicator. Generate NH_3 gas by boiling conc. NH_4OH in the test tube and fill the dropper bottle by inverting it over the 6 mm delivery tube. Slightly warm the bottle by passing it momentarily through the flame. *At once* invert in trough with cut rubber bulb under the water.

Observations: In a minute the bottle cools slightly. This creates a slight vacuum in the bottle, which sucks a little water into the bottle. At once NH_3 dissolves in the water creating a considerable vacuum, and the water spurts up as a lively fountain. As the NH_3 dissolves, the phenolphthalein turns red.

Note: Instead of using the normal glass dropper, as shown in the figure, a variation is to draw it into a nozzle only 1-in. long. When this is used, the water that sucks in quickly covers the nozzle, but the fountain still persists, rushing up *through* the water and spouting lively in the rapidly-filling bottle.

Figure 113. The ammonia fountain.

Dem. 114—Insoluble Hydroxides

To show: The formation of insoluble hydroxides.

Materials: 1 Molar aqueous solutions of NaOH, $FeCl_3$, $FeSO_4$, $CuCl_2$, $CoCl_2$, $NiCl_2$, $ZnCl_2$, $AlCl_3$; cell C-3, stirrer.

Procedure: Use the following very dilute solutions. Fill the culture chambers of C-3 two-thirds full of water, then add reagent as indicated, finally adding the NaOH dropwise to precipitation. Stir toward end of reaction. (*a*) Two drops $AlCl_3$. (*b*) Six drops of $FeCl_3$ or of $FeSO_4$. (*c*) Two dropperfuls of $CuCl_2$, $NiCl_2$, or $CoCl_2$. (*d*) Quarter of a tubeful of $AlCl_3$.

Observations: Good precipitates form. Those with Zn^{++} and Al^{+++} redissolve when excess NaOH is added.

Note: If the dropper containing the NaOH is immersed in the solution, the formation is oftimes more colorful, as the color spreads out from the nozzle of the dropper.

3. REACTIONS OF ACIDS AND BASES

Recall the actions of acids on metals (Dem. 70) and of Al on hydroxides (Dem. 75).

Topic "Water, Acids, Bases, Salts" continued in January 1964 issue.

The Projector

New, improved, completely assembled, this Alyea-approved low-cost projector is the **ideal** instrument for the "TESTED OVERHEAD PROJECTION SERIES" in chemistry.
All of Professor Alyea's demonstrations can be projected quickly, easily. The stage is vertical, students see "live" in color the macro-reaction demonstrations clearly. The unit is sturdy, with glass — not plastic — lenses. Light source is ordinary outdoor flood lamp. The projector is easily portable as the lamp housing forms the carrying case.

The Devices

Hundreds of different experiments can be performed with this thoughtfully-chosen **basic assortment** of devices. Ready for use . . . chemical reactions, gas effects, electro-chemical experiments. The devices stand vertically in front of the condenser lens. Focusing is simple. The assortment includes cells C-1 single cell, C-2 double cell, C-3 triple cell, E-1 electrical cell, E-1A Electrode set (CU, ZN, PB), E-2A half cell inserts, E-3A gas generator inserts, E-4A wire plater inserts, and E-5A migration cell insert.

New! Manostat **EZ-Lock Clamps** for laboratory support frames

It's easy! Manostat's newly developed EZ-Lock Clamps let you say goodbye to tedious set-screw tightening, screwdriver groping, misplaced tools. With the ingenious new EZ-Lock, just a quick turn of the handle and the clamp is tightened securely with vise grip to **two** rods at the same time. Disassembling is equally easy: to release rods, simply turn the handle the opposite way. Clamp will not mar or scratch, cannot stick. Machined of rustproof aluminum alloy, with plastic cap on handle for sure, comfortable grip. New EZ-Lock Clamps are thoroughly compatible with the present line of Manostat Clamps and Support Frames, thus assuring fast, easy mounting of setups virtually custom-designed to your own specific requirements.

See your local laboratory supply dealer.

Write for **EZ-Lock Clamp** bulletin.

When writing for additional information about new products or for new literature, your inquiry will receive prompt attention if you write on your firm or Institution letterhead and mention the Journal of Chemical Education and the date of the particular issue. Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ A special resealable, pressure-release vent is incorporated in a new reduced cost, rechargeable, nickel-cadmium battery, the DR-120 cell, introduced by Gulton Industries, Inc., 212 Durham Ave., Metuchen, New Jersey. Physically it is interchangeable with standard "D" size cells.

▶ Barnstead Still and Sterilizer Co., 168 Lanesville Terrace, Boston 31, Massachusetts, announces the development and introduction of the Barnstead "85" automatic distilled water center consisting of Still with exclusive high purity features and totally enclosed as a cabinet model occupying exactly 36 in. of wall space with work counter at dado height.

▶ Phoenix Precision Instrument Co., 3803–05 N. Fifth St., Philadelphia 40, Pennsylvania, announces its new Model K8000-B a completely self-contained, yet most accessible, instrument for automatic separation, identification, and quantitation of amino acids and related compounds. It features a new dual-speed strip chart recorder for operation with new Accessory 8800-B Accelerated Analysis System, which allows three complete protein or peptide hydrolysate analyses per day.

▶ Laboratory Furniture Co., Inc., Mineola, Long Island, New York, offers the Series FH-300 fume hoods designed to reduce laboratory air conditioning and heat losses.

▶ For nuclear magnetic resonance spectroscopy a new low-cost digital computer, the Mnemotron Cat 400 (NMR), using the averaging technique greatly increases signal-to-noise ratio. Write for *Technical Application Bulletin No. 3* to Mnemotron Division of Technical Measurement Corp., 202 Mamaroneck Ave., White Plains, New York.

▶ For complete data on the rack-mounted V.O.M.-5 Strip Chart Recorder write for *Bulletin D-2046*, Bausch and Lomb Inc., Rochester 2, New York.

▶ Schoeffel Instrument Co., 355 Hillsdale Ave., Hillsdale, New Jersey, offers the new TM 100 Motion Transducer. Descriptive bulletin is available.

▶ A thermoelectric Immersion Cooler which weighs $2^1/_3$ lb is $12 \times 2^3/_4 \times 1^1/_8$ in. and can be successfully used as an "inside-out" refrigerator. Information is available from Whirlpool Corp., Benton Harbor, Michigan.

▶ A new low cost method, the PLE-400 Paper Chromatograph for accurate quantitative analysis of organic or inorganic fluids in industrial, food processing, medical, and many other fields of chemical laboratory work is announced by Possis Machine Corp., 825 Rhode Island Ave., Minneapolis 26, Minnesota.

▶ The American Agile Co., 5461 Dunham Rd., Cleveland 37, Ohio, has just announced a new line of "Agile Vaneaxial Fans." These high-performance, corrosion-proof, long-life fans are the result of two years of intensive research by the company's air engineers and plastics engineers. Constructed of fire retardant, highly chemical resistant polyester resin, they are competitively priced even with ordinary steel fans.

▶ Mixing Equipment Co., Inc., Mt. Read Blvd., Rochester 3, New York, has expanded its line of continuous Lightnin

- Glass clear
- Chemically inert
- Tough
- Flexible
- Easy to handle

Tygon Tubing, Formulation R-3603, is the original transparent plastic tubing specifically developed to handle virtually every laboratory requirement. Flexible as string, Tygon makes tough lab. set-ups easy. Its glass-clear transparency permits better process control. Now in standard use among laboratories all over the world, versatile Tygon Tubing is available in more than 60 sizes.

Look at this finish! The uniform smoothness of this stopper results from brand new molds and equipment.

Research gave it greater rubber formulation. Result: It is softer, more resilient; seals better.

And it's safer. Resilience makes it easy to use with glass tubing, prevents breakage and freezing.

The softer bounce of more rubber provides resistance to set and deformation. It's non-blooming.

It's longer lasting, too — has longer shelf-life with minor (if any) change in hardness.

Illustrated is our basic BLACK RUBBER stopper (#M29). This stopper answers the bulk of laboratory requirements, at low cost. Yet even here, MP quality has evolved a **superior** stopper. Consider the improvements in other grades: Isoprene PURE GUM (#M18) that floats; sulphur-free GREEN NEOPRENE (#M35) that resists 150° C temperatures! All come in your choice of solid, one-hole and two-hole types. All are packaged in fifty-pound bulk, five-pound box, and one-pound poly bags. Choose the most convenient combination for your own needs. MP stoppers are available now at your laboratory supply house — part of an exciting, growing line of educational, industrial, and pharmaceutical products. △ The MP triangle molded on top is your sign of a superior stopper. You can trust the triangle.

Line Blenders to include a model for pilot plant or laboratory use. The units, which are available with Lucite tanks for visual studies, produce the same process results as their larger counterparts.

▶ A new low cost infrared spectrophotometer—the first in its class to offer variable slit programing—has been introduced by Perkin-Elmer Corp., Main Ave., Norwalk, Connecticut. The new Model 237B gives the chemical analyst widest possible flexibility in adapating to the requirements of analysis.

▶ A new drum-and-stylus recorder which shows when a given laboratory operation begins and ends has been announced by Henry Troemner, Inc., 22nd and Master Sts., Philadelphia 21, Pennsylvania. Through a display of working time and downtime, the new instrument is said to provide valuable information for the improvement of laboratory work habits and schedules.

▶ A modular gas chromatograph, the Aerograph Hg-FI_2 one of a new Moduline Series, which offers the chemist precisely the instrument of his choice, has been announced by Wilkens Instrument & Research., P.O. Box 313, Walnut Creek, California.

▶ A new line of high temperature, high vacuum furnaces has been announced by the Vacuum Products Division of Varian Associates, 611 Hansen Way, Palo Alto, California. These cold-wall furnaces maintain a pressure of 5×10^{-9} torr while at temperatures above 2000°C. The furnace system rapid-cycles to 5×10^{-8} torr in two hours, and base pressures are below 5×10^{-10} torr.

▶ The new "Widebeta" and "Lowbeta" II radioactivity counting systems, developed by Sharp Laboratories, are now being marketed by the Scientific and Process Instruments Division of Beckman Instruments, Inc., 2500 Harbor Blvd., Fullerton, California. Representing an additional capability for Beckman in the nuclear products field, the systems combine the most recent advances in high sensitivity, low background alpha and beta counting instrumentation.

▶ Detailed technical data concerning Crystalab Deem-a-Flow Series 400 and 500 demineralizers is available upon request. Write to Crystal Research Laboratories, Inc., 29 Allyn St., Hartford 4, Connecticut.

▶ The Micro-V magnetic stirrer with planetary gear-head motor, ideal for setup frames and racks, is announced by Cole-Parmer Instrument and Equipment Co. 7330 N. Clark St., Chicago 26, Illinois. Measuring only $2^3/_4$-in. square and 5-in. high, the stirrer is designed to fit handily in small spaces.

A Laboratory Glass Cutting Unit
Welch HOT-WIRE GLASS-TUBING CUTTER

Produces Clean, Straight Breaks
Cuts Hard or Soft Glass with equal facility

Glass tubing, bottles, or jars up to 3 inches in diameter can be cut neatly and quickly with this cutter. Soft glass, Pyrex-Brand Glass, or other hard-glass tubes can be cut with equal ease. The article is first encircled with a scratch made by a cutter wheel conveniently mounted on the side of the transformer, the scratch is heated by contact with the hot wire, and then cooled quickly by applying water or by blowing on it. No other equipment is required.

The cutter wire is supported on two insulated posts and is heated by current from a 12-volt transformer serving as the base. No. 24 (B & S gauge) nichrome wire is used and is easily replaced. Three extra wires are included. By means of an adjustment on the transformer, the current can be controlled to give the optimum heat for whatever type of glass may be used. An instruction plate is mounted near this control. The unit operates on 115 volts, 50 or 60 cycle A.C. Over all dimensions are $6 \times 4^1/_2 \times 9$ inches high.

What happened to the Class of '60?

Harlan Marsh Baxter

Jerry Dale Shay

James P. Silver

Richard D. Seiler

Harlan Baxter is with Olin's Chemicals Division, developing commercial applications for the new wonder-fuel, hydrazine.

(We're working on new products that would make an alchemist scoff in disbelief.)

Jerry Shay was recently promoted to Technical Advisor in Olin's Metals Division.

(We're moving so rapidly, we haven't had time to master the art of red tape.)

Jim Silver is designing ammunition processing machinery for Olin's Winchester-Western Division.

(One of 6 diversified divisions in 6 major growth industries.)

Richard Seiler is a Research Supervisor in Olin's Packaging Division.

(Research gets a healthy budget, research people, a healthy climate.)

Right now, Olin is looking for the class of the Class of '64. For complete information, the man to contact is Monte H. Jacoby, College Relations Officer, Olin, 460 Park Ave., New York 22, N.Y.

▶ A new precision solid-state scaler, SC-520 Series, has been introduced by the Tracerlab Division of Laboratory For Electronics, Inc., 1601 Trapelo Rd., Waltham 54, Massachusetts. The new scaler features high-voltage power supply, decade scaler, electronic timer, and data readout. The Series SC-520 Omni/-Guard Scalers feature anticoincidence circuitry which permits the lowest possible background count.

▶ A line of 11 corrosion-resistant stainless steel sample, one and two valve cylinders are offered by The Matheson Company, Inc., P.O. Box 85, East Rutherford, New Jersey. They are fabricated from 304 stainless steel, finely machined, ICC approved and suitable for the sampling, transportation, and storage of products under pressure.

▶ Unicam Instruments, Ltd.'s new Sp. 200 Infrared Spectrophotometer provides the ultimate in performance, speed, and reliability in the low cost infrared field. The SP. 200 is the only spectrophotometer in its price range with a variable slit program, or program energy control. For complete information, write either: Unicam Instruments, Ltd., Cambridge, England, or Wilkens-Anderson Co., 4525 W. Division St., Chicago 51, Illinois.

▶ Yellow Springs Instrument Co., Box 106, Yellow Springs, Ohio, announces the release of a new all solid state proportional controller, the YSI Model 72. The Model 72 has direct digital dialing of set point which is settable and resettable to ±0.01°C. Short-term stability is ±0.005°C and long-term stability is ±0:01°C. The proportioning band is adjustable from 0.1 to 3°C to allow optimization of the controller response to the control situation.

▶ Representing the most modern, precision Wheatstone Bridge available today, Leeds & Northrup's all-new #4289 D-C Wheatstone Bridge offers convenient, on-the-spot measurement of resistance in research, design, and quality control applications, with laboratory accuracy. For complete information, write Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia 44, Pennsylvania.

▶ Central Scientific Co., 1700 Irving Park Rd., Chicago 13, Illinois, has introduced three new single pan analytical balances for both routine laboratory and high-accuracy analytical weighing. The new balances have capacities of 160 and 200 g with sensitivities of 1.0 and 0.1 mg.

▶ *Bulletin CA-1* of Kontes Glass Co., 126 Spruce St., Vineland, New Jersey, describes the Chromaflex Chromatographic Columns with removable fritted

BUDGET-PRICE JEM-T6 ELECTRON MICROSCOPE: 20 A RESOLUTION . . . 30,000X MAGNIFICATION Available in the U.S. and Canada only from Fisher Scientific, the JEM-T6 electron microscope guarantees resolving power of better than 20 A and achieves 12 A. Direct magnification: 500X to 30,000X. The JEM-T6 is a true electromagnetic microscope at a price which equals or beats that of less satisfactory instruments. Perfect for industrial quality control work. Excellent for classroom teaching and practice. Ideal for specimen review. If you want a compact, even lower priced electron microscope, Fisher recommends the JEM-T1. Resolution: 50 A; direct magnification: 5000X. Both microscopes are available under terms of the new Fisher Financing Plan. **For more facts** about the microscopes and the Financing Plan, write Fisher Scientific Company, 109 Fisher Building, Pittsburgh 19, Pa. disks, extendable lengths, "Teflon" stopcocks, removable reservoirs and "O" ring joints.

▶ For complete information and descriptive literature on the Sievert Welding Torch for plastics, write Nalgene Piping Systems, 75 Panorama Creek Dr., Rochester, New York, 14625.

▶ Soft X-ray measurements originating from the K and L shells of low atomic number nuclides are summarized in a set of data sheets and actual graphs offered by Nuclear Measurements Corp., 2460 N. Arlington, Indianapolis, Indiana, 46-218. The measurements illustrate a new simple technique of producing and measuring these soft X-rays. The results, presented on graphs calibrated directly in KEV, were produced by the Model GSS-1B gamma analyzer.

▶ Carle Instruments, 532 S. Rose St., Anaheim, California, announced availability of a new Micro-Thermal Conductivity Detector System for use in small column gas chromatography. Consisting of a detector block and a separate control unit, the new detector system can be installed easily in any commercial or laboratory-assembled gas chromatograph.

▶ The newest member of the DigiTec family of instruments is the low cost Model "900" AC-DC Converter, featuring 0.3% accuracy for AC inputs up to 500 V, covering a frequency range of 50 CPS to 25 KC. This new instrument has 4 ranges: 1–10–100 and 1000 V full scale, with input impendance of 1 Meg + 47 pf. Its output impendance is 10 K with a 1-sec reading time reponse. Write United Systems Corp., 918 Woodley Rd., Dayton 3, Ohio, for details.

▶ Laboratory Plasticware Fabricators, 615 Wyandotte, Box 213, Kansas City, Missouri, offers color coded Teflon Coated "Spinbars."

▶ A convenient means of handling Dewar flasks safely and quickly in laboratory assemblies is offered by The S/P VacRac. It consists of a nylon fiberglas plate with built-in support rod and stainless steel hinge. At push of a lever, plate swings down, out of way. Distributed by Scientific Products, 1210 Leon Pl., Evanston, Illinois.

CENCO'S NEW ANALYTICAL BALANCES

A. SOLID TITANIUM BEAM / JEWELED MECHANISM: beam surfaces can't flake—lose weight—as do plated beams. Synthetic ruby knife on synthetic sapphire plane, jeweled bearings at all critical points for long-term accuracy. **B. POSITIVE, CHAIN-DRIVEN WEIGHT CONTROL:** stainless steel chain not affected by environment or age, no cord-and-pulley drive to slip. Ring weights are stainless steel, corrosion resistant, non-magnetic, precisely calibrated. NBS Class "S" weights used in models 1581 and 1582; "S-1" in model 1580. **C. ALL-METAL HOUSING:** durable, rugged, minimum dust attraction. Heavy, multiple-coat baked enamel finish. **D. EASY-VIEW WEIGHING CHAMBER:** non-corroding base impervious to chemical attack. Crystal clear glass walls highly resistant to scratching, will not discolor. **E. EFFICIENT, NON-FATIGUING CONTROLS:** simple, speedy operation through natural, straight-line movement of operator's hands from side loading of sample to controls manipulation. With hands off to side, operator always has clear view of readout. **F. EASIER, MORE ACCURATE READOUT:** fixed vernier with cursor for quick, accurate readout.

WHAT GOES ON HERE?

If you do any chromatography at all, it should be the new Lab-Crest needle valve, designed especially for your use. It's not a make-do adaptation, but a brand-new design with the precise control and reproducibility you need.

It takes 12 turns of the new valve to get from positive-zero close to unimpeded (3 mm) open—and there's a reference scale on the stem for hairline accuracy.

The valve will never freeze, never need grease. Its body is precision-bore glass tubing; its needle, Teflon.

You can have the valve either by itself or built right into one of our new chromatography-column bottom connections. (The new connections are more than pretty good themselves: minimum volume between the removable fritted disc and the valve keeps the effluent you're working with from remixing.)

All things considered, the built-in's your best bet, but if you just want the valve itself, fine. We'll be glad to oblige. If you'd like information on either the valve, the bottom connections, or both, let us know.

Bronwill brings you Godfrey Stereomodels

Can you match these Stereomodels with their correct names? See bottom of page.

SEE SKELETAL STRUCTURE...ACTUALLY MEASURE INTERNUCLEAR DISTANCES

GODFREY STEREOMODELS are of tremendous importance to teachers, students and research chemists. They present chemical relationships better than ever before possible. You can see skeletal structure . . . how atoms are linked . . . whether they are stable . . . and why. You can even measure internuclear distances with remarkable accuracy . . . a precise, 250,000,000× magnification of all elements is ingeniously maintained (2.5cm = 1Å). Bond angles are correct, too. Elements are all vividly, solidly and permanently colored throughout . . . and virtually unbreakable, too! Free rotation about single bonds is demonstrable . . . yet structures will remain locked in any preset position. Boat or chair conformation of cyclohexane show their natural stability . . . even intermediate twist conformations can be fixed in position for handling and measurement.

The basic kit is supplied, at no extra charge, with a large variety of structural components . . . olefinic and aromatic double bonds, acetylenic triple bonds, the benzene ring, amide and nitrile groups, as well as tetrahedral and trigonal carbon and nitrogen, digonal oxygen and sulfur, hydrogen and the halogens . . . at a price, one-third of any competitive units. No tools are required for any assembly . . . simple, quick, hand connections only. Connector tubes have positive, snap-lock connections, with built-in torsional friction. Large, complex models (synthetic polymers, proteins, polysaccharides) can be assembled and handled without inadvertent disruption.

STEREOMODELS IN TOP PHOTO: A. Methylacetylene; B. α Phenoxyethyl Penicillin; C. *cis* Decalin; D. Bicyclo [2,1,1,0^{5,6}] hexane-5 (N-t-butyl) carboxamide; E. 6-Trifluoromethyl -7-sulfamyl-3,4-dihydro-1,2,4-benzothiadiazine 1,1-dioxide.

It would have been easier if they were visible in their full, identifying colors. Write today for full color brochure.

BRONWILL No. 90, GODFREY STEREOMODELS . . . Complete Kit, $49.95 each (lots of 12—$45.00, lots of 24—$40.00)

KEEP PURE WATER PURE TO POINT OF USE

WITH BARNSTEAD TIN LINED PIPING

With Barnstead Tin Lined Piping you can distribute distilled or demineralized water to any point in your plant or laboratory without fear of contamination. Combining the desirable characteristics of pure tin plus the strength and durability of metal pipe, tin lined piping, fittings and valves can be enclosed in floors or walls permanently. Gooseneck faucet with self-closing handle may be either wall or bench mounted.

Faucets come complete with accessories for through-wall mounting.

Tin lined pipe is standard weight brass pipe lined with pure block tin 1/16" in thickness. Tin threads on pipe are screwed into tin threads within the fitting to insure tin-to-tin contact. No special tools or skills are needed. No plumbing problems.

NEW BULLETIN #180 describes the complete line of Barnstead tin lined pipe, fittings, faucets and valves. Write for your copy today. Consult Barnstead, Pure Water Specialists since 1878.

A NEW IDEA IN WATER STILLS FOR 1964

BARNSTEAD "85"

DISTILLED WATER CENTER

Here's a complete, totally enclosed Distilled Water Center. It is a complete, self-contained package producing higher purity distilled water for all laboratory and research needs. Requires no manual attention. Automatic controls produce and store distilled water around the clock, dispensing it at its own work counter. Maintenance is completely eliminated since the Still never needs cleaning. Needs only 3 feet of wall space. Designed to blend in with Laboratory counters and casework. Ideal for low ceilinged Research and Lab rooms, yet delivers distilled water at working height. No special mountings are needed and installation is easy and inexpensive. The Barnstead "85" has many exclusive operating features including automatic temperature controls and direct reading Purity Meter.

Specifications and information detailed in Bulletin #191. Write for your copy today. No obligation and it will be mailed promptly.

BARNSTEAD'S NEWEST

WATER DEMINERALIZER CARTRIDGE

1. Provides low cost deionized water for small volume or infrequent users.
2. No equipment expense. 30% to 50% lower cost per gallon than with other brands.
3. Hose nipples at both ends for easy connection to faucet and collection vessel with ordinary laboratory tubing.
4. Can be used on closed systems under pressure up to 25 psig. Flow rates, up to twenty gallons per hour.
5. Complete line includes Oxygen Removal, Organic Removal and other special types.
6. No meter or electrical connections needed. Clamps onto Lab stand, or bracket is available for wall mounting.
7. Backed by over 85 years of specialized water purification experience.

WRITE: Bulletin #190

THE
HOT-SHOT Jr.
SUSSMAN
ELECTRIC BOILER

the compact source of steam... ideal for hundreds of laboratory uses

Only 20" high and 12" wide—the Hot-Shot Model MB-3 electric boiler is light and small enough to be portable. Put it anywhere in your lab. Connects to any water source, plugs into 110V or 220V line, gives you full steam in just five minutes with the flick of a switch. Completely automatic. Delivers 10 lbs. of steam per hour.

Additional models available to deliver up to 666 lbs. of steam per hour at pressures through 250 P.S.I. — 407°F.

Suggested Uses: **Carrier Gas in Gas Chromatography** • Sterilizing Equipment • Autoclaves • Jacketed Equipment • Lab Steam Baths • Steam-Cleaning Small Parts • Pilot Plant Installations.

chemicals is identified by the letter prefix "G" which identifies the means of final purification: gas chromatography.

◇ The Radiochemical Division of Nuclear-Chicago Corp., 359 E. Howard Ave., Des Plaines, Illinois, announces the availability of Uridine-5-T with a specific activity of 13 curies/mM. The highest specific activity previously available was 3 curies/mM.

◇ Lachat Chemicals, Inc., 10540 Southwestern Ave., Chicago 43, Illinois, offers *Supplement No. 1* to their regular catalogue of products and materials for research. These include column packing for chromatography, non-aqueous solvents for potentiometric titrations and new chemical standards.

Miscellany

★ A scientific recruiting service, believed to be the first of its kind in the country, has been formed in Minneapolis, specifically designed to help industry and business overcome the perennial problem of finding qualified personnel to fill specialized technical positions. Called Dyna-Search Control, Inc., the company is using modern communications facilities in conjunction with a high-speed computer system to compile, analyze, and rapidly supply requesting companies with data on available specialists in virtually all technical areas. Dyna-Search's facilities include a Control Data 160A computer system and the Bell Telephone System's new Model 35 automatic send-receive teletypewriter which, in addition to hard copy, produces eight-level punched tape, compatible with computerized operations. The company has developed a special translation system which converts an applicant's qualifications into a numerically coded "knowledge pattern," capable of being evaluated by the computer.

★ General Electric recently announced that it has developed a new rapid-charge battery—a sealed, maintenance-free, nickel-cadmium cell—which holds major promise both for space uses and for powering portable tools and appliances. Time required for recharging the new battery is sharply reduced, and the battery itself is lighter than conventional sealed cells. The practical result is that battery-operated equipment now can be designed for almost continuous use—with only brief intervals required to recharge the battery.

★ The Chicago Gas Chromatography Discussion Group will hold its second annual gas chromatography course at Roosevelt University, Chicago, Illinois, on January 28–31, 1964. The course will include laboratory sessions and a textbook as well as lectures. The tuition is $40. Write to Dr. R. E. Dedmon, 1753 West Congress Parkway, Chicago 12, Illinois for additional information.

COLEMAN

Metrion® II.. versatile, low-cost pH measurement

All routine pH measurements—even those requiring temperature compensation—can now be performed with a simple, low-cost pH meter, the Coleman Metrion II

This precision meter incorporates such premium features as temperature compensation control and automatic - titrator - connections. The large selection of Coleman electrodes further extends the Metrion II's range to include unusual samples, sample sizes and temperatures.

Designed for accuracy and reliability—as well as for economy—Metrion II has simple controls and trouble-free printed circuitry. Priced at $179 (including electrodes and buffers), it features:

- Accuracy—0.05 pH
- Range—0-14 ph
- Temperature Compensation—0-100° C
- Stabilized Operation—110-130V AC

Cat. No. JC-65429 . . . . . $179.00

DRIERITE®

"The Versatile Desiccant"

For Drying
SOLIDS—LIQUIDS—GASES
in
INSTITUTION—INDUSTRY
LABORATORY—PLANT

Efficient—Dries all organic liquids instantly in liquid or vapor phase. Gases retain only 0.005 mg. H_2O per liter.

Versatile—An all-purpose desiccant.

Non-Wetting—Does not become wet on saturation nor crystallize to wall of tubes, towers or desiccators.

Neutral—Dries without reacting with either acid or alkaline materials.

Inert—Except toward water. Does not decompose, polymerize, or catalyze organic substances by contact. Insoluble in organic liquids.

Regenerative—Repeatedly after any normal use, by dehydration at 200 to 225°C.

Economical—Lowest priced high grade desiccant. Available in quantity for Industrial Processes.

Chem Ed

EDITORIALLY SPEAKING

Scientific Communication

The Journal of Chemical Education has as its purpose the systematic presentation of chemistry in a coherent, understandable form. With new facts and theories being published faster than anyone can read and assimilate the flood, effective systematization is an indispensable service. It seems appropriate in this connection to raise for reemphasis a few old but very practical questions.

Since English is being ever more widely employed as the language of science, we have additional reasons for improving its effectiveness. Both French and Spanish were reformed in days gone by being made phonetic and by acquiring a simplified spelling. Theodore Roosevelt made a gallant effort to simplify spelling in this country. The net result was a few changes in place names and one more proof that reforming English is like straightening the channel of the Mississippi. One should either leave it to regulate itself or find a way to get concerted action. When I enquired as to whether the ACS Journals might not be strong enough to initiate some spelling reforms, it was pointed out that our journals have problems enough without adding all-out spelling reform. Nevertheless, we ought to go as far as we prudently can to make scientific English shed some of its more archaic forms. Anyway, it is fun to watch the purists wrestle with some of the quaint forms introduced into the mother tongue by some not too skillful translators. To these unhappy purists it should be remarked that imperfect translations are usually much more usable than no translation. In any case we should expand our support for English resumés of foreign language articles and help in every useful way to make English as serviceable as we can as a medium of international communication.

Such thoughts inevitably lead to the ageless question, "Why does anyone tolerate the English system of weights and measures?" There seems to be no logical answer. Presumably no one would seriously argue that the metric system would not be greatly superior. It will be expensive to change over but the price is not apt to get less by waiting. The conclusion to such considerations seems inescapable. We should make the change! A rapid change would probably be cheapest, but as that seems impractical we should at least hurry the inevitable change as much as we can. Dr. Douglas V. Frost in a letter to *C & E News* (October 21, p. 4) makes a strong case for the changeover. Among other things he lists a sizable part of our economy which is already committed to the metric system.

Scientific instruction already uses the metric system. We should likewise use the metric system in instructing college students in engineering. This closer liaison between fundamental science and engineering would at least partly offset the disadvantage of a movement away from industry. One result of this would be that the rising generation of engineers, trained in the metric system, would be alert to opportunities to guide new developments into adopting the better system.

Next, we should start writing engineering specifications in the metric system as well as the English system with a reasonable target date at which time the English system is to be phased out. The government and the more alert segments of industry should take the lead in the changeover with some offering of incentives in cases where the change would cause extraordinary hardship. The change in the writing of specifications need only involve using one or two more decimal points and the actual changes in design could come as dictated by economics. Obsolescence in many industries is such that a changeover in fifteen or twenty years would minimize the economic losses.

Fundamental to the above suggestions and to others such as calendar reform is the underlying fact that all forms of communication are continually undergoing changes which adapt them better to the conveying of information. No one minds this change very much as long as it does not become too conspicuous. However, it is just those procedures which are most used and are therefore most deeply ingrained where simplification and rationalization will be most profitable and where the changes will also be most stubbornly resisted by those who stand to lose by the change. Changes in procedures should be carefully thought through so that as nearly as possible every one profits by the reform, but continual evolution and change cannot be avoided in scientific matters. Research is in fact dedicated to the discovery of useful changes. Ira Remsen and even G. N. Lewis would find a lot of interesting, but to them puzzling, reading in a current number of THIS JOURNAL. This is as it should and must be.

Criteria for Experiments in Radiochemistry

When Becquerel discovered radioactivity in 1896 (*1*), a new phenomenon was added to those which were then considered to constitute the science of chemistry. Today the various aspects of radioactivity, as they relate to chemistry, are identified with the area of specialty known as radiochemistry. During the first four decades of radiochemistry, radiochemists were concerned mainly with the discovery (*2*), identification, separation, purification and uses of the naturally occurring radioelements (*3*, *4*). A few experiments utilizing the new radioelements as indicators were introduced into college chemistry courses (*5*). Following the discovery of the neutron (*6*) by Chadwick in 1932 and of artificial radioactivity (*7*) by Curie and Joliot in 1934, the scope of radiochemistry expanded to encompass the entire periodic table, as it was then known. Within a few years several hundred radionuclides had been identified and characterized (*8*, *9*). As the number of chemists with experience in the production and, in particular, the utilization (*10*) of radioisotopes grew, the interest in introducing experiments in radiochemistry into chemistry courses in colleges and universities also grew. Apart from photographic film or plates, the instruments available for radioactivity measurements for educational purposes at that time were often limited to various types of electroscopes (*5*, *11–14*). These were and still are (e.g., pocket dosimeters) extremely valuable detectors although limited with respect to sensitivity. Geiger tubes and scalers were in many cases homemade and were nursed along primarily for use in research.

The current era of radiochemistry began about 1939 with the discovery of nuclear fission by Hahn and Strassmann. This was followed in 1940 by the discovery (*15–17*) of elements beyond uranium in the periodic table, namely, neptunium by McMillan and Abelson and plutonium by Seaborg, McMillan, Kennedy, and Wahl. The impact of these discoveries on college chemistry curricula did not begin, however, until after World War II. As a result of the Manhattan Project, there came into being a relatively large community of scientists who were experienced in a wide variety of new techniques and methods of producing, separating, and using radioactive materials. Many scientists returned to academic institutions with interests stemming from their wartime experiences. Declassification of reports began and the facilities of some of the national laboratories became available for the education of college faculty members. Centers for training in radioisotope techniques were established (*18*, *19*). Such wide-scale dissemination of information would not have been effective had there not been a simultaneous improvement in the availability of radioisotopes and instrumentation for radioactivity measurement. Reactor-produced radioisotopes, including fission products, were made available as byproduct material in various forms at a nominal cost. Research reactors and plutonium-beryllium neutron sources capable of inducing radioactivity became available to colleges and universities. Concurrently, the nuclear instrumentation industry grew in magnitude from its small pre-war size to the comparatively large and com-

---

Sponsorship of Committee on Nuclear Science—NAS-NRC

The Subcommittee on Radiochemistry is one of a number of subcommittees working under the the Committee on Nuclear Science within the National Academy of Sciences-National Research Council. Its members represent government, industrial, and university laboratories in the areas of nuclear chemistry and radiochemistry.

One of the interests of the Subcommittee is the place of radiochemistry in college and university programs. Previously, a cross-referenced index of published radiochemical teaching experiments was issued as NAS-NRC Publication 905. To further aid the instructor in deciding the value and the feasibility of including radiochemical experiments in his course, the Subcommittee is collaborating with the Journal of Chemical Education in sponsoring publication of a series of new radiochemical experiments. The primary aim of this series is to point out unique advantages of radiochemical experiments for instructional purposes and to furnish to the instructor of inorganic, analytical, physical, organic, and biochemistry a variety of radiochemical experiments for his laboratory program.

We would welcome contributions to this series as well as suggestions and comments from the readers relative to the question of radiochemical instruction, particularly in the undergraduate curriculum. Suggestions and comments should be addressed to Prof. G. R. Choppin (Department of Chemistry, Florida State University, Tallahassee, Florida), who is representing the Subcommittee on Radiochemistry and is coordinating its activities in this area.

N. E. Ballou, *Chairman*
Subcommittee on Radiochemistry

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

petitive industry which exists today. To assist in the acquisition of irradiation facilities and nuclear instrumentation for use in college courses in science and engineering, the U. S. Atomic Energy Commission and the National Science Foundation have made equipment grants to educational institutions and have supported the preparation and publication of teaching experiments (*20*).

Several books (*21–31*) containing procedures for experiments in radiochemistry have been published and numerous articles describing specific experiments, the teaching of nuclear chemistry or radiochemistry (*19, 32–42*), or uses of radioisotopes in chemistry (*10, 43–48*) have appeared in THIS JOURNAL. The Subcommittee on Radiochemistry of the Committee on Nuclear Science of the National Academy of Sciences—National Research Council has issued two reports (*49, 50*) relating directly to the teaching of radiochemistry and a series of monographs on the radiochemistry of the elements and on radiochemical techniques (*51*). These monographs contain ideas, methods, and procedures which could be adapted for use in teaching experiments.

Today, then, with an increasing number of college faculty members having some knowledge of and experience with radioisotope techniques, and with instruments, radioisotopes and published experiments being relatively available, the introduction of one or more aspects of radiochemistry into the chemistry curriculum is becoming commonplace. Two distinct ways are used to introduce radiochemistry into the chemistry curriculum. One is by means of a course in radiochemistry. Such a course deals with the more sophisticated methods and techniques described in a number of special laboratory textbooks and is usually taught by a specialist. The second way is by introducing one or more experiments in radiochemistry in some of the regular chemistry courses. It is the latter approach which is given the emphasis in this paper. By drawing attention to certain aspects of experiments in radiochemistry the author hopes to encourage others to design new experiments, modify published experiments, and in a general way extend the usefulness of their nuclear instruments.

The Nature of Radiochemistry

For the sake of discussion, radiochemistry is taken to encompass both the chemistry of radioactive substances and the application of radioisotopic tracer techniques to the study of phenomena associated with the various branches of chemistry. Since radiochemistry is a blend of the classical subdivisions of chemistry, it is not surprising that the techniques of radiochemistry are utilized in connection with the research and teaching activities in these subdivisions, e.g., analytical, bio-, general, inorganic, instrumental, organic, and physical chemistry.

It is important to recognize that radiochemistry differs from stable-isotope chemistry in several ways. For example, since radioactive decay is a non-equilibrium process, time becomes an important experimental variable. In extreme cases the half life may be so short that the radionuclide cannot be isolated and studied radiochemically; or the half life may be so long that the radionuclide, e.g., Th^{232}, can be considered to be "stable" in terms of chemical manipulation.

In radiochemistry it is common to encounter a separation problem involving a mixture of elements having atomic numbers differing by only one or two units. Such mixtures may be produced during the irradiation of a target or may arise from decay of a radionuclide to form a radioactive daughter as in the fission product series or in the naturally occurring series. Although a parent-daughter relationship between radioelements or between isomers of the same element may introduce undesirable radiochemical complications, it may have practical advantages in some cases. Thus, a long-lived parent is often a convenient source of a very short-lived daughter or the radiation emitted by the daughter may enhance the detection and usefulness of the parent radionuclide.

Under suitable conditions the means of detection and measurement of the radiation emitted by a radioactive substance are so sensitive that chemical phenomena may be studied at extremely low concentrations or for extremely small quantities of material. Examples of the uses of radioisotopic tracers are well known. It should be noted, however, that at exceedingly low concentrations, chemical behavior, as observed radiochemically, may differ significantly from that at macro concentrations (*52*).

There are at least two additional ways in which radiochemistry differs from the chemistry of nonradioactive substances. The first is with respect to chemical purity. In terms of the detectable number of atoms of a contaminant, radiochemical purity can be much more stringent than ordinary chemical purity, and the radiochemical purity of a sample may increase or decrease with time. Secondly, the nuclear radiation which provides the basis for the methods of instrumentation used in radiochemistry also creates the problem of radiological; it may, by ionization and excitation processes, induce chemical reactions, e.g., radiolysis, which can complicate the chemical behavior of a sample of radioactive material.

In the design, selection, or evaluation of teaching experiments in radiochemistry several obvious criteria should be considered. The objectives of the experiment should be consistent with the objectives of the course, the experimental techniques required should be consistent with the level of the course and the previous experience of the students, and the experimental procedures must be consistent with safe handling techniques.

It is generally true that the introduction of an experiment or experiments using radioactivity into an established course can be done only by substitution. The difficulty and the justification of such substitution vary with the level and type of course. Although the difficulty may be greatest at the first-year level, an elementary course may be the only chemistry course which a student takes, and it may, therefore, be the course which provides a basis for his understanding of the phenomenon of radioactivity in our nuclear age. This is particularly true in a small liberal arts college. In any case, the introduction of experiments in radiochemistry into the chemistry curriculum should not be based on fashion but rather on recognition of the educational value of such experiments.

Objectives of Laboratory Experiments in Radiochemistry

Any experiment in radiochemistry provides the student with a laboratory experience in the handling of radioactive material and in the measurement of radioactivity. These are general objectives. In addition, any experiment has one or more specific radiochemical objectives which relate the experiment to a topic or topics in the course. The specific objectives will be used in this paper as a basis for classifying experiments in radiochemistry.

One specific objective, for example, would be to illustrate an aspect or several aspects of the chemistry of radioactive substances, e.g., the preparation, separation, purification, characterization, identification, or assay of radionuclides in various chemical forms. In an experiment having this objective the major emphasis would be on the phenomenon of radioactivity and such an experiment would be introduced on the basis of a belief that radioactivity per se is sufficiently important in the field of chemistry to share in the already crowded schedule. Included in this category would be radiochemical separation of two or more radionuclides followed by an evaluation of the effectiveness of the separation; determination of the half life of a radionuclide by decay measurement or specific activity measurement; characterization of the radiation emitted by a radionuclide; investigation of the properties of the radioelements, including the transuranics (*53*); preparation of carrier-free radionuclides by the Szilard-Chalmers reaction (*54, 55*); and utilization of radioactivity for age determination.[1]

A second specific objective would be to illustrate the use of radioisotopic tracers to provide a more convenient or a more sensitive means for determining the amount or concentration of a substance. Examples of such experiments would be the determination of solubility, common ion effect, and heat of solution (*56–58*); measurement of the distribution between immiscible solvents (*59, 60*); study of chemical reaction rates; evaluation of effectiveness of chemical separation methods (*61, 62*); determination of stability constants for complexes (*63*); radiometric analysis (*64*); activation analysis; study of diffusion; study of adsorption; measurement of surface area; determination of atomic weight, measurement of blood volume (*65*); study of biosynthesis (*66*); etc.

A third specific objective would be to illustrate one or more of the unique applications of isotopes (although not necessarily radioisotopes). Examples of effects which may be measured by the use of isotopes are exchange reactions between different chemical species of an element (e.g., species differing with respect to the oxidation state of a given element) (*67, 68*); exchange reactions between species in different phase states (e.g., a solid salt and its ions in solution) (*69*); certain types of reaction mechanisms, self-diffusion, the isotope effect, and isotope dilution (e.g., isotope dilution analysis). "Tagged-atom" experiments would fall in this category. In general the reaction, process, or effect is studied by measurements which reflect a change in the isotopic ratio of the labeled element.

A fourth specific objective, which is related to the first one, would be to show by an error analysis how the results obtained in the experiment are influenced by the statistical nature of radioactive decay and nuclear radiation detection (*70, 71*). This aspect of radioactivity should receive some attention in any teaching experiment in radiochemistry. The relative importance assigned to it will depend on the background of the students and on how complete an analysis of experimental data is required of the students.

In the foregoing discussion it is implied that an experiment having the second or third objective would be used by an instructor to emphasize the principles involved in the use of radioisotopes in the study of chemical phenomena. To the extent that it is feasible to do so, the radioisotope would probably be selected so that radioactive decay would not complicate the experiment and the radiation measurements would be relatively simple. Although the particular chemical phenomenon would probably be familiar to the student, an objective of the experiment would be to improve the student's understanding of the chemistry involved. On the other hand, the primary educational aim of the instructor might be to introduce a fundamental concept or principle of chemistry more effectively through the use of radioisotopes. A related aim would be to use radioisotopes to effect a saving in teaching time. The appropriate experiments would be similar to those having the second or third objective, but the emphasis would be different. There would be less emphasis on radioisotope methodology.

Finally, there are two areas of chemistry, namely, nuclear chemistry and radiation chemistry, in which the experimental research can involve radioactive materials and can require the use of radiochemical procedures. In some cases, then, a teaching experiment in either of these areas could also be considered an experiment in radiochemistry. For example, a specific objective, which is becoming important as theories of life become more detailed, would be to study the chemical effects of radiations from radioactive material, e.g., radiolysis, Szilard-Chalmers effect, etc. Such experiments in radiation chemistry often require relatively large amounts of activity. When this is the case, they would best be performed as part of a course in radiochemistry, with adequate hazard control equipment and shielding facilities.

Experimental Techniques

The problems of introducing experiments in radiochemistry into a first year chemistry course are certainly different from those encountered for an upper-class course in, for example, instrumental analysis. For the latter, an experiment in radiochemistry may simply provide laboratory experience in one of a wide variety of specialized instrumental methods of analysis. At the first year level, however, one cannot expect the student to follow a procedure requiring sophisticated techniques. The problem is further complicated by the fact that the student may not have had any high school chemistry experience. Furthermore, there is always the possibility that the purpose of the experiment may be obscured by a procedure unnecessarily complex for the level of the course. Simple procedures and techniques are preferable from the point of view of

[1] The paper by Fairhall appearing in this issue, J. Chem. Educ., 40, 626 (1963) illustrates this topic.

Digitized by Arya Samaj Foundation Chennai and eGangotri

both the student and the instructor. At this level and even through the senior year one is dealing primarily with ideas, concepts, and principles rather than techniques. These should be introduced as simply and directly as possible but without misleading the student by oversimplification. This does not imply that a student should not be required to learn techniques, and it does not overlook the fact that the success of an experiment depends upon the procedure and techniques used. However, the educational value of an experiment is not lost if, for example, a simplified radiochemical separation procedure which takes only 10 min instead of 30 min and requires relatively inexpensive chemical apparatus results in a yield and purity of only 50 and 75%, respectively, instead of 85 and 90%.

There are many ways in which the procedures and techniques for undergraduate radiochemical experiments can be simplified by making use of techniques used for non-radiochemical experiments. For example, it is questionable whether mastery of the technique of using a micropipet and micropipet control is essential in an experiment in an elementary course. Such precision apparatus is properly associated with radiochemistry and its use is not questioned when the success of an experiment depends upon it. It is not sacred, however, and can often be replaced by the humble and more familiar medicine dropper. The latter is far less delicate than a micropipet and is less costly (about $^1/_{100}$ of that for a micropipet plus its control). If desirable, a dropper can be calibrated rapidly in fractions of a milliliter and marked with a file. Furthermore, the tip can be adjusted in a flame to give volumes in the range of 10 to 40 λ drop and, of course, solution concentration can be adjusted for further control. Finally, the placing of a contaminated rubber bulb in a waste storage vessel is less difficult than the decontamination of a pipet control.

A wide variety of other commonly available inexpensive apparatus may also be used effectively in radiochemical experiments. The familiar dropping bottles, test tubes, and centrifuges used for semi-micro qualitative analysis are suitable for experiments involving low levels of radioactivity. Two criteria should be used in the selection of such apparatus. Obviously, the first is that it must be suitable for the proposed chemical manipulation. The second, which narrows down the choice, is that it must be suitable for use in the safe handling of radioactive materials. As a conservative guide in visualizing safety problems it is often helpful to apply the same stringent tests that would be applied to apparatus used for the safe handling of bacteria. This implies that use of the apparatus will not result in the contamination of the student's hands, will not release airborne activity, will not lead to ingestion of activity, will not result in a spreading of activity throughout the working area, and will not result in contamination of the counter. Accordingly, in handling radioactive liquids it is best to avoid tall, top-heavy vessels and vessels having glass stoppers or stopcocks through which leakage is very likely to occur. A simple screw cap vial can often serve as a mixing vessel such as might be used for solvent extraction. A soft metal foil liner (e.g., lead, tin, or aluminum, depending on possible reactions involving the foil) in the cap helps to make a tight seal. Obviously care must be used in venting volatile solvents when a vessel containing a radioactive material is opened.

Pipetting of liquids of any kind by mouth should be strictly forbidden (as should be the case in any chemistry laboratory). Rather inexpensive rubber bulbs can be used with normal size pipets. Radioactive liquids should not be caused to spatter and should not be boiled in open vessels. The latter includes planchets or dishes used for counting. A liquid sample can be evaporated to dryness in a planchet by means of heat lamp which is placed at a distance that is reasonable in terms of the volatility of the liquid. In general, if one avoids handling radionuclides in a volatile or potentially volatile form, there is little need to require a hood for a radiochemical experiment involving a few hundredths of a microcurie of activity. Even with a hood, one would avoid releasing radioactive halogens, volatile radioactive organic compounds, and radioactive gases such as CO_2 and H_2S which might be released by thermal dissociation or acidification of radioisotopically labeled carbonates or sulfides.

Planchets containing radioactive material should be handled with forceps such as the type having medium fine, curved points. The forceps alone should not, however, be used to carry the planchet about the laboratory. To reduce the chance of dropping the planchet, a source holder, i.e., the holder used to position the source beneath an end-window detector, or a small flat plate or tray, should be used to support the planchet when it is being moved.

Consistent with good housekeeping, the laboratory working surface should be kept clean with an easily removed covering of plastic or paper. Inexpensive trays or rectangular glass dishes of the household type are helpful for confining a spill of liquid. All bottles and storage vessels containing radioactive material should be properly labeled in accordance with governmental regulations. This includes, of course, the containers for radioactive liquid waste and for solid waste. Suitable labels, tags, and printed adhesive tape are commercially available from a number of suppliers of laboratory equipment for radiochemistry.

The safe-handling problem varies depending on the chemistry of the experiment, the quantity of radioactivity involved and the particular radionuclide or radionuclides being used. Thus, in separating solids and liquid, centrifugation is generally preferable to filtration because of the greater difficulty in controlling filtration with respect to recovery of material, spread of contamination, etc. Filtration is sometimes unavoidable as, for example, in the preparation of certain sources for counting. Special filtering apparatus (of which several types are commercially available) and careful techniques are required because of the nature of this mechanical separation process.

Quantity of Radioactivity and Choice of Radionuclide

Several factors combine to determine the quantity or radioactivity used in a teaching experiment. Although millicurie quantities of a radionuclide might be available as material produced locally with an accelerator or a research reactor, or as licensed by-product material, or as naturally occurring material, the quantity

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

handled by a student in a teaching experiment should be limited by radiological safety requirements to the minimum necessary to obtain meaningful results. Neither an experiment requiring the use of an exceptionally hazardous radionuclide nor one for which the minimum quantity is of the order of a millicurie would be an attractive experiment in a regular undergraduate chemistry course. In the case of radionuclides produced with a small (α,n) source or available as "generally-licensed" or "exempt" quantities of byproduct material, the limitation in quantity used is often controlled by the limited supply. Generally-licensed quantities, commonly limited to a few microcuries, do not require a specific license. They are specified by law and are under the regulation of either the federal or the state government, depending upon the state. Generally-licensed quantities together with the half life and information about the radiation emitted by each radio-nuclide are listed in Table 1. A number of these radionuclides are available in generally-licensed quantities from commercial suppliers[2] as indicated in Table 1. It should be noted that the use of generally-licensed quantities does not entitle one to ignore the practices of safe handling.

[2] A list of suppliers may be obtained from the U. S. Atomic Energy Commission, Division of Isotopes Development, Washington 25, D. C. Most of the companies that sell the instruments and laboratory equipment used for work with radioactive materials also sell the radioisotopes. In addition, there are companies that specialize in radiochemicals. Suppliers are also listed in "The Isotope Index," published by the Scientific Equipment Co., P. O. Box 19086, Indianpolis 19, Ind.

All other β, γ emitting material: 1 μc[i]				
Alpha emitting material: 0.1 μc				

[a] Not as a sealed source.

[b] For byproduct material, based on the Federal Register Title 10, Chapter 1, Part 30 (October 17, 1957) and the New York State Sanitary Code Chapter 1, Part 16 (October 15, 1962). No person is allowed at any one time to transfer, receive, possess or use more than a total of ten generally-licensed quantities.

[c] E_{max} in Mev for only the predominant beta radiation—of interest in selecting a counting procedure. A number in parenthesis indicates low intensity. Negatron emitters unless otherwise indicated.

[d] β^+ emitter.

[e] α emitter.

[f] Radionuclide listed in the New York Sanitary code but not in the Federal Register.

[g] γ indicates emission of γ rays; (γ) indicates low intensity. Characteristic X-rays are indicated when electron capture is not accompanied by γ emission.

[h] Radionuclide is one of those readily available commercially; often sold as part of a set or source kit of generally-licensed material.

[i] Examples of other radionuclides available as generally-licensed, 1 μc quantities are Sb^{125}, Ba^{133}, Co^{57}, Mn^{54}, Hg^{203}, Ag^{110m}, and Sr^{85}. Pb^{210} (a source of Bi^{210} and Po^{210}) is available in 5 μc quantities.

When there are several radionuclides suitable for use in an experiment, it is advantageous to choose one with a half life not over a few weeks. The apparatus becomes self-decontaminated in a reasonable length of time and the accumulation of radioactive waste does not become a problem. If needed, however, radioactive waste disposal service is available commercially and it is usually feasible to cooperate with other users of radioactivity on campus in employing such service.

For experiments illustrating a method of radiochemical separation, the generally-licensed quantities are usually adequate. There are also several naturally occurring radionuclides which are suitable. One might use perhaps 1–5 times as much as is needed for counting, i.e., a total of about 0.03μc, to obtain a final counting rate of about 1000 cpm. If a radiochemical separation is to be followed by half life determination in the same laboratory period, the time required for the separation and subsequent source preparation must be short. Commonly, but not necessarily, this means a separation by precipitation or solvent extraction. Separation by ion exchange can be rapid when volumes are small. Ion exchange, adsorption, solvent extraction, electrolysis, or precipitation have all been used in experiments involving the separation of a short-lived daughter from its long-lived parent, e.g., UX_1 from U^{238} (*12, 14, 44, 72–75*); UX_2 from UX_1 (*72, 74, 75*); Ba^{137m} from Cs^{137} (*76, 77*); Pb^{207m} from Bi^{207} (*78*); ThB from ThX (*79, 80*); ThC from ThB (*79*); La^{140} from Ba^{140} (*81*); Pr^{144} from Ce^{144} (*82*); and RaE and RaF from RaD (*83, 84*). Thin layer chromatography and filter paper chromatography (*83–85*) are worthy of serious consideration in experiments illustrating radiochemical separation. Although filter paper chromatography, for example is relatively slow, an adequate separation of two radionuclides can often be obtained in less than an hour if ΔR_f for the elements involved is large. Chromatographic methods are inherently simple, and since they require no attention, the students can be conducting other experimental work concurrently. The chromatogram can be sectioned for counting or it can be scanned with an end-window detector (or a cylindrical detector if the radiation is sufficiently penetrating). A simple scanner can be made with a ruler, a scanning slit (e.g., 2 mm) cut in a piece of metal such as lead and interposed between the chromatogram and the detector, adhesive tape, a piece of wood or heavy cardboard, a laboratory clamp with holder, and a ringstand.

Relatively few of those generally-licensed radionuclides which are currently readily available are suitable for the determination of a half life by decay during a single 3-hr laboratory period. In general the activity should be followed for at least two half lives for a sample known to contain only a single radionuclide. For a sample containing long-lived activity as well as the short-lived one to be measured, the decay should be followed until the longer-lived component or components predominate. Allowing for time to prepare a source for counting, the upper limit of half life for measurement during a single 3-hr laboratory period is about 1 hr. The lower limit, assuming a relatively simple counter consisting of a Geiger tube in combination with a scaler or a ratemeter, is about 1 min. Both generally-licensed and naturally occurring radionuclides require radiochemical separation of the desired short-lived nuclide from a long-lived parent.

When an accelerator, nuclear reactor, sub-critical assembly, or (α,n) source is available, several radionuclides suitable for half-life determination can be produced. An (α,n) source, e.g., Pu-Be or Ra-Be (*86*), is convenient for the production of a limited number of radionuclides for low level work. By judicious choice of target material, one can often use the induced activity without radiochemical separation. A selected list of short-lived radionuclides, including two which are naturally occurring, is given in Table 2. This list is limited to those radionuclides for which there is no special problem in readily obtaining target materials or long-lived precursors. Vorres (*87*) has given a detailed description of neutron activation with a Pu-Be source and has listed the initial activities attainable for a number of radionuclides.

Table 2. Selected Beta and Beta-Gamma Emitters with Half Lives Between 1 Min. and 1 Hr.

Radionuclide	Half life (min)	Method of production
Pa^{234} (UX_2)	1.18	Nat.; sepn. from Th^{234} (UX_1)
Al^{28}	2.27	Al(n,γ), Al(d,p), Mg(α,p)
Ag^{108}	2.3	Ag(n,γ), Ag(d,p), Pd(p,n)
Ba^{137m} [a]	2.60	F.P.; sepn. from Cs^{137}; Ba(n,γ)
Cu^{66}	5.10	Cu(n,γ), Cu(d,p), Zn(n,p)
Mg^{27}	9.45	Mg(n,γ), Mg(d,p)
Pr^{144}	17.5	F.P.; sepn. from Ce^{144}
Br^{80}	17.6	Br(n,γ), Br(d,p), Se(p,n)
C^{11}	20.4	C(n,2n); B(d,n); B(p,n)
I^{128}	24.99	I(n,γ), Te(d,2n), Te(p,n)
Cl^{38}	37.29	Cl(n,γ), Cl(d,p),
In^{116m}	53.93	In(n,γ), In(d,p), Cd(p,n)
Bi^{212}(ThC)	60.5	Nat.; sepn. from Pb^{212} (ThB)

[a] Gamma only

Many applications of radioisotopes which one might like to exemplify in a teaching experiment normally require amounts of radioactivity of the order of a few tenths to several millicuries. Appropriate experiments are to be found in laboratory courses in radiochemistry since it is in such courses that the techniques for handling millicurie amounts are presented. When the level of radioactivity is limited entirely to generally-licensed quantities and when many students are involved, the design of a suitable experiment becomes a challenge. In fact, one must often be prepared to tailor the teaching experiment to fit the radionuclide. In research one tries to avoid this limitation. Consider, for example, the use of radioisotopes in the determination of the solubility of a slightly soluble substance. The advantage of the tracer method for analysis in this case can be readily understood in terms of its sensitivity. An experiment dealing with solubility, ionic equilibrium, the common ion effect, etc. is appropriate in a variety of courses. There is no difficulty in preparing a list of substances which are slightly soluble in a common solvent such as water. Yet, relatively few are attractive for a teaching experiment with generally-licensed quantities. A few simple calculations will show why. One must first estimate the quantity of radioactivity required in order that significant results can be obtained with the counting equipment available.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

In its simplest form, the experiment consists of (1) measurement of the radioactivity concentration of the tracer solution to be used, (2) preparation of a few milligrams of labeled solid of known specific activity usually predetermined by the amount of tracer solution used, (3) equilibration of the labeled solid with a solvent (or solution containing a common ion, for example), and (4) measurement of the radioactivity concentration of an aliquot of the saturated solution. Measurements of the activity of the original tracer solution and of the final saturated solution are made in an identical manner, i.e., as a solid after plating or evaporation of the solvent in a planchet, or as the liquid using a suitable Geiger or scintillation counter.

Taking as an example an unshielded, thin-window Geiger counter having a background counting rate of about 30–50 counts per minute, one finds that counting errors associated with the statistical nature of radioactive decay have a strong influence on the results when measurement times are limited to a few minutes and when the counting rate in excess of background for the sample is much less than 300—500 counts per minute, i.e., about ten times background. If the counting conditions are favorable, i.e., high sensitivity of the counter for the radiation, high energy radiation attenuated to a negligible degree by the window, and negligible self-absorption in the source, then it is feasible to expect an overall detection efficiency of 10–20%. Assuming that the lower limit is more realistic, the sample of saturated solution taken for counting should have at least 3000–5000 disintegrations per min, corresponding to about 0.002 μc. If the volume of liquid in equilibrium with the solid is as small as 10 ml and if a 1 ml sample is taken for counting, the 10 ml of solution would contain about 0.02 μc. If the solubility of the substance is 1 mg per 100 ml of water, for example, the specific activity of the substance must be 0.2 μc per mg. Preparation of a sample of the labeled solid weighing only 25 mg will require 5 μc of activity. The lower the solubility of a substance is, the higher is the specific activity necessary because only a fraction of the total activity in the system is in solution and available for measurement. This is quite apart from any aliquoting involved in sampling the saturated solution. In actual applications of the tracer method, higher counting rates are desirable, and the necessary quantity of radioactive material is used. The solubility of calcium sulfate in water is sufficiently high (300 mg per 100 ml) to make its determination feasible (within the limits of reaching equilibrium, etc. in a three-hour period) with generally-licensed quantities. Similarly, the solubility of lead iodide (40 mg per 100 ml of water) can be measured by the use of I^{131}. Sometimes a solubility-type experiment becomes feasible when a complexing agent is present or when the temperature is somewhat above room temperature. The latter variation, of course, introduces the added complication of requiring a temperature-controlled apparatus.

Starting with an estimate of the amount of radioactivity needed for measurement and following a similar approach based on a knowledge of the chemical phenomenon involved, one can estimate the total amount of activity needed for any type of experiment. For radionuclides emitting low-energy beta radiation, e.g., C^{14}, S^{35}, losses in detection efficiency resulting from self-absorption in the counting source and window absorption must be compensated for by using more activity. In the case of C^{14}, the losses of beta radiation by absorption in a counter window are approximately 23, 40, 55, and 65% for window thicknesses of 1.0, 2.0, 3.0 and 4.0 mg/cm^2, respectively. Tritium, although available as a generally-licensed radionuclide, emits such low-energy radiation that relatively sophisticated techniques and rather special detection instruments are required.

The design of experiments requiring only small quantities of radioactive material has been receiving attention, e.g., (*20, 23, 24, 41, 57, 85*), and progress has been made in this direction. Further effort is needed. As already pointed out, however, the level of radioactivity required is not the only factor which determines the usefulness of an experiment. An experiment requiring only a low-level quantity of radioactivity is not a good experiment for a regular undergraduate chemistry course if it involves procedures, techniques, and apparatus used by a specialist who has a well-equipped radiochemistry laboratory at his disposal. There is need for improvement in this direction. Many of the experiments which have been published over the years can be modified for use with reduced quantities of radioactive material and with simplified radiochemical procedures. In some cases the counting procedure can be improved by counting liquid samples of gamma emitters with a well-type scintillation detector of the type which has become available for teaching purposes.

Other Aspects

The design of an experiment in radiochemistry can be strongly influenced by the way in which the experiment is scheduled in a course. In much of the foregoing discussion it is implied that the experiment is to be completed in a single laboratory period. Such is the case when the apparatus and instruments are used by a different student or team of students each period as in a course involving hundreds of students. When the scheduling permits a student to use the apparatus and instruments for more than one period, certain advantages accrue. Somewhat longer-lived radionuclides (*88*) can be used for half life determinations, filter paper chromatography can be combined with autoradiography, etc.

Despite the limitations of a single three-hour laboratory period, much can be accomplished. At Rensselaer, for example, the students in first year chemistry currently conduct two experiments in a single period. One consists of a rapid separation of Pr^{144} from Ce^{144} followed by a determination of the half life of Pr^{144}. The second consists of a tracer experiment in which Bi^{210} is used in determining the distribution of bismuth between two solvents.

It is difficult to relate the dollar cost to the value of an experiment but the relationship cannot be overlooked. The cost of nuclear instrumentation suitable for basic experiments, e.g., detector with scaler or ratemeter, is rather uniform. Sometimes savings can result from choice of detector. If one is not using a radionuclide such as C^{14} or S^{35}, there is little justification for employing an end-window detector with an especially thin window. These special detectors are more costly and will require replacement more often

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

because they are more fragile. Glassware and apparatus normally carried in the stockroom should be used whenever possible. Radiochemistry does not inherently require the use of costly apparatus. Students should be impressed by the function of the equipment, not its elegance.

Demonstration Experiments

Most of the foregoing also applies directly to radiochemical experiments designed for lecture or classroom demonstration. New problems arise, however, because of the limited time available for the demonstration and because of the challenge of conveying the nature and progress of the experiment to the spectator. The second complication becomes severe when there are several hundred students in the lecture hall. Where available, closed circuit television is helpful, of course. In general the requirements are (1) a simple and yet striking illustration of the phenomonon (2) a clearly visible or audible indication of the phenomenon and (3) relatively inexpensive apparatus. The counting equipment which probably comes closest to meeting these requirements consists of a Geiger tube and a ratemeter equipped with a loud speaker. The counting rate can be recorded on the blackboard as a quantitative confirmation of the qualitative audible signal experienced by the students.

In designing a lecture experiment one has the advantage of being able to incorporate techniques consistent with the skill of the lecturer. The classification of experiments previously mentioned still applies. Thus the combination of a radiochemical separation followed by determination of a half-life by decay, e.g., the separation of the element protactinium as Pa^{234} (UX_2) from uranyl nitrate and determination of its half life (1.18 min) has been used by the author. Tracer experiments such as those involving isotope exchange or dynamic equilibrium as for a solid salt in contact with a solution can also be used effectively for lecture demonstration.

Dating of Uranium Minerals by the Specific Radioactivity of Lead

This paper discusses a method for estimating the age of a uranium mineral without recourse to elaborate mass-spectrometric techniques.[1] The method is admittedly a very crude one; however, its purpose is not intended to be an alternative to the more accurate dating methods based on lead isotope ratios. Instead it serves as the basis for a few simple radiochemical manipulations, which are instructive in themselves, and as an illustration of the principle of age determination of a mineral via radioactivity. The required manipulations are fundamental to radiochemistry and at the same time so simple that the outlined experiments are suitable for use at the undergraduate or senior high school level. Only very rudimentary equipment is required, consisting of a Geiger counter, a set of aluminum absorbers, and a few elementary pieces of chemical apparatus. The raw material for the experiment, pitchblende ore, is readily obtainable from mineral specimen supply houses and only a small quantity is required per student. Reagent grade uranyl nitrate, available from a number of chemical supply houses, is the only other special chemical which is needed.

As outlined in detail below, the experiment is carried out in two parts, each of which may be completed in a 4-hour laboratory period. The second part is optional and the teacher may instead provide the students with the information (the counting efficiency of the counter) afforded by doing this part of the experiment. It is suggested that the students work in pairs. In addition to the regular laboratory period it will generally be advantageous if the students can have access to the counting equipment for about 3 to 4 weeks in order to measure periodically the radioactivity in the samples; however, only one measurement can suffice for the first experiment provided it comes at least 5 days after the chemical separation.

The teacher will recognize that in addition to the two experiments outlined below there are other experiments which the student may perform using the same

[1] An experiment developed at the request of the Subcommittee on Radiochemistry of the Committee on Nuclear Science, NAS-NRC, as part of a series illustrating radiochemical techniques and their applications.

Digitized by Arya Samaj Foundation Chennai and eGangotri

radioactive samples. These include (a) studies of backscattering of β radiation by various thicknesses and various kinds of material, (b) the determination of a decay curve, (c) determination of the complete absorption curve of a sample for an estimation of the range of a given β emitter, (d) separation of Bi^{210} from Pb^{210} by a variety of techniques. The pitchblende ore is a rich source of other radioelements which the student can isolate, for example, radium and polonium, and it can serve as the starting point for other radiochemical experiments.

The dating method has been tested on a few minerals which have been accurately dated by mass-spectrometric techniques.[2] These specimens were furnished through the courtesy of Professor Wallace R. Broecker and Mr. Ian G. Swainbank of the Lamont Geophysical Observatory. Samples of these minerals were given to a class of 12 students in the author's senior-level laboratory course in radiochemistry. The results are tabulated in Table 1. It is seen that rather good agreement between this method and the known age of the minerals was achieved in a few instances, and even in the poorest cases the results are "in the right ball park."

Table I. Results Using Mineral Specimens of Known Age

Student group	Sample no.[a]	Age of mineral (in yrs)	Age, this method (in yrs)
1	K 6	6×10^7	14×10^7[b]
2	K 19	8×10^8	6.9×10^8
3	K105	3.4×10^8	3.8×10^8
4	K105	3.4×10^8	2.9×10^8
5	K120	1.6×10^9	1.7×10^9
6	K120	1.6×10^9	1.2×10^9

[a] Sample designations as given in footnote 2.
[b] This specimen is particularly young and contamination by non-radiogenic lead is relatively severe, amounting to 72% of the lead content. Allowing for this fact, the apparent age which is outained is close to the value to be expected by the present method.

Isolation of Radiogenic Lead and Measurement of Its Beta Activity

Consider a uranium mineral, such as pitchblende (U_3O_8) for example, which at some time, t, in the past has crystallized or otherwise been deposited in solid form. If at the time of deposition a fractionation occurred such that the uranium-bearing mineral was formed free of lead, either "ordinary" lead or lead which had formed prior to t through radioactive decay of uranium, then decay of the uranium subsequent to time t will result in an accumulation of lead in the uranium mineral. Radioactive decay of uranium produces lead through two long sequences of α and β decays. A few key steps in these sequences are as follows:

$$U^{238} \xrightarrow[4\beta\text{'s}]{7\alpha\text{'s}} Pb^{210} \xrightarrow{\beta} Bi^{210} \xrightarrow{\beta} Po^{210} \xrightarrow{\alpha} Pb^{206} \text{ (stable)}$$

$$U^{235} \xrightarrow[4\beta\text{'s}]{7\alpha\text{'s}} Pb^{207} \text{ (stable)}$$

At the present time uranium is made up of 99.28 atom per cent U^{238} and 0.72 atom per cent U^{235}. Because these two isotopes of uranium have different half lives (U^{238} 4.5×10^9 yrs; U^{235} 7.1×10^8 yrs) their relative numbers of atoms change with time. If we consider 100 n uranium atoms now, where n is some unspecified but very large number, then we have 99.28 n atoms of U^{238} and 0.72 n atoms of U^{235}. According to the laws of radioactive decay, t years ago there were $99.28\ n\ e^{\lambda_{238} t}$ atoms of U^{238} and $0.72\ n\ e^{\lambda_{235} t}$ atoms of U^{235}. Here λ refers to the decay constant of the radionuclide in question and is numerically equal to 0.693/half life. Since the total weight of each uranium isotope is proportional to the number of atoms and their atomic weights, the proportionality constant being the reciprocal of Avogadro's number N, we can write

$$\text{Wt } U^{238}(t) = 99.28 \cdot \frac{n}{N} \cdot 238\, e^{\lambda_{238} t} \text{g} \quad (1)$$

$$\text{Wt } U^{235}(t) = 0.72 \cdot \frac{n}{N} \cdot 235\, e^{\lambda_{235} t} \text{g} \quad (2)$$

Evidently the difference between the weights of uranium isotopes at time t given by these expressions and the corresponding weights of uranium isotopes present now, $99.28 \cdot n/N \cdot 238$ g and $0.72 \cdot n/N \cdot 235$ g, respectively, represents the weight of the uranium isotopes which have disintegrated in the intervening t years. Thus

$$\text{Wt } U^{238} \text{ disintegrated} = 99.28 \cdot n/N \cdot 238(e^{\lambda_{238} t} - 1)\text{g} \quad (3)$$

$$\text{Wt } U^{235} \text{ disintegrated} = 0.72 \cdot n/N \cdot 235\,(e^{\lambda_{235} t} - 1)\text{g} \quad (4)$$

According to the decay sequence of the radioactive species, each 238 grams of U^{238} which disintegrate gives 206 grams of Pb^{206}, the remaining mass being that of the α particles which were emitted. Likewise each 235 grams of U^{235} gives 207 grams of Pb^{207}.

Thus we can write for the weight of accumulated lead isotopes in the mineral

$$\text{Wt } Pb^{206} \text{ accumulated} = 99.28 \cdot n/N \cdot 238(e^{\lambda_{238} t} - 1)\frac{206}{238}$$

$$= 99.28 \cdot n/N \cdot 206(e^{\lambda_{238} t} - 1)\text{ g} \quad (5)$$

$$\text{Wt } Pb^{207} \text{ accumulated} = 0.72 \cdot n/N \cdot 235(e^{\lambda_{235} t} - 1)\frac{207}{235}$$

$$= 0.72 \cdot n/N \cdot 207(e^{\lambda_{235} t} - 1)\text{ g} \quad (6)$$

The ratio of equation (5) to equation (6) is seen to be a function of t, and hence the ratio Pb^{206}/Pb^{207} is a sensitive measure of the age of the mineral. However the determination of this ratio requires mass-spectrometric techniques. The present simplified method is based on the *sum* of equations (5) and (6):

$$\text{Total wt Pb accumulated} = \frac{n}{N}\,[99.28 \times 206(e^{\lambda_{238} t} - 1) + 0.72 \times 207(e^{\lambda_{235} t} - 1)]$$

$$= \frac{n}{N}\,[2.05 \times 10^4(e^{\lambda_{238} t} - 1) + 1.49 \times 10^2(e^{\lambda_{235} t} - 1)]\text{g} \quad (7)$$

The weight of accumulated lead in comparison with the weight of uranium remaining in the mineral may be expressed as the ratio:

$$\frac{\text{wt accumulated Pb}}{\text{wt of U remaining}} = \frac{\frac{n}{N}\,[2.05 \times 10^4(e^{\lambda_{238} t} - 1) + 1.49 \times 10^2(e^{\lambda_{235} t} - 1)]}{\frac{n}{N}\,[99.28 \times 238 + 0.72 \times 235]} =$$

$$0.858(e^{\lambda_{238} t} - 1) + 6.26 \times 10^{-3}(e^{\lambda_{235} t} - 1) \quad (8)$$

This ratio is plotted in Figure 1 for various values of the time t. It will be seen from this figure that for minerals less than about 70×10^6 years old the radiogenic lead is less than 1% by weight of the uranium present. Such young minerals are more difficult to date by the present simplified method, requiring somewhat larger samples in order to have sufficient recoverable lead; and the results are more sensitive to traces of non-radiogenic lead in the mineral.

Figure 1. Ratio of the weight of accumulated lead to the weight of uranium remaining as a function of the age of the mineral.

In equation (7) we have neglected the weight of Pb^{210} formed as an intermediate because it is present in exceedingly small amount, by weight. In terms of its radioactivity, however, it gives the same number of disintegrations per unit time as does the U^{238} in the specimen, the reason being that the decay sequence is in a state of secular equilibrium. This means that for each of the species in the sequence the rate of formation is equal to the rate of decay, and a steady state exists.

In the example which we are considering, namely $99.28 \cdot n$ atoms of U^{238} present now, the decay rate of Pb^{210} in the sequence is equal to the decay rate of U^{238}, which in turn is given by

$$\text{decay rate } U^{238} = \lambda_{238} \times 99.28 \cdot n \text{ atoms dis per sec.} \quad (9)$$

This is also the disintegration rate of Bi^{210}, the species formed by decay of Pb^{210}.

Suppose, however, that we now make a chemical separation of lead from the mineral, leaving behind all other elements, radioactive or otherwise. Approximately three hours after the chemical separation, the radioactivity in the purified lead is just that of Pb^{210}.[3] However, the decay of Pb^{210} produces fresh Bi^{210} which soon accumulates in sufficient amount to contribute its own radioactivity to that of the Pb^{210}; after a few weeks the Bi^{210} and Pb^{210} have come into secular equilibrium with each other and both have the same decay rate. The equation which gives the growth of Bi^{210} activity with time is given by the expression

$$\text{d/sec } Bi^{210} = \text{d/sec } Pb^{210}\,(1 - e^{-\lambda_{Bi^{210}} T}) \quad (10)$$

[3] At the time of the chemical separation there is present also 26.8 m Pb^{214}, the antecedent of Pb^{210}. This activity and its immediate decay products soon decay completely to Pb^{210}.

where T refers to time after chemical isolation of lead from the mineral in the laboratory. Therefore the total radioactivity of the lead isolated from the mineral is

$$\begin{aligned} \text{d/sec (total)} &= \text{d/sec } Pb^{210} + \text{d/sec } Pb^{210}(1 - e^{-\lambda_{Bi^{210}} T}) \\ &= \text{d/sec } Pb^{210}(2 - e^{-\lambda_{Bi^{210}} T}) \\ &= \lambda_{238} \times 99.28 \times n(2 - e^{-\lambda_{Bi^{210}} T}) \end{aligned} \quad (11)$$

In both of the expressions (10) and (11) we are considering times T of the order of one month, which is short relative to the half life of Pb^{210} (19.4 yr). That is, for a time short relative to the half life of Pb^{210} the change in the disintegration rate of Pb^{210}, and hence in the equilibrium value of Bi^{210}, is insignificant.

Let us now consider the *specific activity* of the isolated lead fraction. Specific activity is defined as the number of radioactive disintegrations per unit time per unit weight of a substance. In our present example this is given by the ratio of equation (11) to equation (7):

$$\text{Specific activity of lead} = \frac{\lambda_{238} \times 99.28 \times n(2 - e^{-\lambda_{Bi^{210}} T})}{\frac{n}{N}\,[2.05 \times 10^4(e^{\lambda_{238} t} - 1) + 1.49 \times 10^2(e^{\lambda_{235} t} - 1)]}$$

$$= \frac{\lambda_{238} \cdot N \cdot 99.28 \times (2 - e^{-\lambda_{Bi^{210}} T})}{2.05 \times 10^4(e^{\lambda_{238} t} - 1) + 1.49 \times 10^2(e^{\lambda_{238} t} - 1)} \quad \text{d/sec g lead} \quad (12)$$

Note that in this expression the quantity n has cancelled from numerator and denominator. Since this quantity represented essentially the amount of uranium being considered in our example, its cancellation from the equation means that *the specific activity of lead* given by equation (12) *is independent of the amount of uranium under consideration.* It is also independent of the efficiency with which the lead can be recovered from the mineral. The specific activity of lead isolated from a uranium mineral depends only on the time, t, since the mineral was deposited lead-free in nature and the time T following the chemical isolation of lead from the mineral in the laboratory. Curve A of Figure 2 is a graph showing the specific

Figure 2. Specific activity of lead separated from a uranium mineral as a function of time after the separation. Curve A refers to the total radioactivity in the lead, curve B to the radioactivity due to Bi^{210} only. Secular equilibrium is attained after about 1 month.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

activity of the lead as a function of T. The secular equilibrium value is reached after about one month.

In practice, the *observable* specific activity of lead isolated from a uranium mineral is due soley to the Bi^{210} daughter of Pb^{210}. The reason is that the radiations emitted by Pb^{210} are so low in energy that essentially none of them penetrate the usual type of detectors used to measure the radioactivity. On the other hand, the radiations of Bi^{210} are sufficiently penetrating that practically all of them are detectable. Therefore, the observed specific activity of purified lead follows curve B in Figure 2 rather than curve A, and at secular equilibrium the observable specific activity is one-half of that given by equation (12):

$$\text{Observed specific activity of lead at equilibrium} = \frac{\lambda^{238} \cdot N \cdot 99.28}{2.05 \times 10^4 (e^{\lambda 238 t} - 1) + 1.49 \times 10^2 (e^{\lambda 235 t} - 1)} \text{ d/sec g lead} \quad (13)$$

The observable specific activity of chemically isolated lead, due only to Bi^{210}, is plotted in Figure 3 as a function of the uranium mineral formation time, t, for various times T after the isolation of lead. By the use of this graph the age of a uranium mineral may be determined by observation of the radioactivity associated with lead isolated from the mineral.

In all of the preceding it has been assumed that the uranium mineral was initially lead-free. If some lead contaminated the uranium mineral when it was formed, then the observed specific activity will be less and the apparent age of the mineral will be older than it otherwise would be if there were no contaminating lead present. A more sophisticated technique involving mass spectrometric analysis of the isolated lead is required for accurate dating of uranium minerals contaminated with ordinary lead. Figure 4 is a graph showing the apparent age versus the true age of a uranium mineral for various proportions by weight of radiogenic lead and contaminating lead in the specimen.

Of course if the mineral incorporated some of its previously-formed radiogenic lead during recrystallization there is no way to determine whether this type of contamination has indeed occurred and an older apparent age will result.

Figure 3. Specific activity of lead isolated from a uranium mineral as a function of the age of the mineral for measurements made at various times T after the time of separation of lead from the mineral.

Experiment Dating Uraninite Minerals

Place a small quantity (about 100 mg) of the mineral in a 15-ml centrifuge tube. Add 10 drops each of conc. HNO_3 and H_2SO_4 and heat to boiling (caution!) over a burner. The U_3O_8 will dissolve readily in this mixture at a rate dependent upon particle size. As the acid boils away replenish with more conc. HNO_3. When most of the mineral appears to have dissolved, evaporate off most of the excess acid, cool, and dilute the mixture to 5 ml with H_2O. Warm the mixture and add 1 drop satd. $Ba(NO_3)_2$ solution (Note 1). Keep the solution hot for a few minutes, then centrifuge the mixture. Decant and discard the aqueous phase. Wash the residue with 2–3 ml of warm H_2O containing a drop of dilute (1:10) H_2SO_4. Centrifuge and discard the washings.

To the residue in the centrifuge tube add 1 ml 6 M NaOH. Disperse the solid with a stirring rod and warm the mixture in a boiling water bath. Dilute to 5 ml with water (stir the mixture) and centrifuge. With an eye dropper pipet transfer the aqueous phase to a clean centrifuge tube.

To the solution add a drop of methyl orange indicator. Acidify the solution by dropwise addition of HNO_3 until the indicator turns from yellow to red (Note 2). Use a stirring rod to mix the solution thoroughly during acidification. Add 1 ml of 0.5 M Na_2SO_4 solution. Warm the solution in a boiling water bath for a few minutes, stirring frequently. Cool under running tap water. Centrifuge the precipitate of $PbSO_4$, discarding the aqueous phase.

Redissolve the precipitate of $PbSO_4$ in 1 ml 6 M NaOH and dilute the solution to 5 ml with water. Stir the solution in the test tube and add 1 drop of 10 mg/ml Fe(III) carrier. Stir vigorously so as to disperse the precipitated $Fe(OH)_3$. Centrifuge the precipitated $Fe(OH)_3$, decanting the solution into a clean centrifuge tube.

Acidify cautiously with HNO_3 using methyl orange indicator in the same manner as before. Add 1 ml of 0.5 M Na_2SO_4 solution. Warm the mixture to coagulate the precipitate of $PbSO_4$. Using a filter-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

stick with chimney arrangement (Note 3), filter the suspension through a 1-in. fine-porosity filter paper which has been previously weighed to 0.1 mg. Wash the precipitate on the paper with water followed by alcohol. Dry the filter paper at 110°C for 10 min. Weigh the dried filter paper after it has stood for 10 min in the atmosphere.

Figure 4. Apparent age versus true age for uranium minerals contaminated with extraneous lead. Curves are given for several fractions, f, of the lead presently in the mineral which was derived from uranium decay since the mineral was formed.

Mount the filter paper for counting, covering the precipitate and filter paper with a thin plastic film. Count the precipitate periodically over a period of about 10 days to establish the growth of Bi^{210} and to enable you to predict the final equilibrium value, A c/s (curve B, Fig. 2) (Note 4).

The counting efficiency of the counter-sample combination must be known. The biggest factor which enters into the counting efficiency is usually the solid angle subtended by the sample and the window of the counter. A simple way to determine this experimentally is given in the second part of this article. If the counting efficiency is known the specific activity of the lead may be calculated from the equation

$$\text{specific activity of lead} = A\ \text{c/s} \times \frac{100}{\text{counting efficiency (\%)}} \times \frac{1.47}{\text{wt}\ PbSO_4\text{(g)}}$$

The factor 1.47 is a gravimetric factor related to the proportion of the $PbSO_4$ precipitate which is Pb. In the present case the atomic weight of the lead is between 206 and 207, depending on the age of the mineral. The uncertainty in the atomic weight of the lead which should be used in this equation makes very little difference to the final result.

The age of the mineral is obtained from the observed specific activity of the lead using the appropriate line in Figure 3.

Notes

1. The barium is added in order to remove traces of radium from the solution by binding it as an insoluble sulfate precipitate. This prevents contamination of the lead sulfate precipitate, recovered in subsequent steps, by radium. The barium sulfate precipitate may also assist in the precipitation of lead sulfate from the solution by isomorphosis substitution of Pb^{++} ions in the $BaSO_4$ lattice.

2. The solution should be only slightly acid; otherwise, excess H_3O^+ ions lower the SO_4^{--} ion concentration by formation of HSO_4^- ions. The solubility of $PbSO_4$ in the solution is then correspondingly increased, resulting in poor efficiency of precipitation of $PbSO_4$ in the next step.

3. This is not a standard item in scientific supply catalogues. The components may be procured from Scientific Glass Apparatus, Inc., Bloomfield, N. J., as follows: the base is made from a Filter Tube (F-3820, 30 mm disc, medium porosity) which has had the rim ground off to make a flat surface. This tube is inserted through a rubber stopper and mounted in a suction flask. The filter chimney ($1.50 each) may be obtained by referring to Print No. 576,141. The filter paper disc, punched from sheets of ordinary filter paper by a 1-in. die punch, is held firmly between the disc of the filter tube and the filter chimney by a #28 clamp (C-5165). The width of the prongs of the clamp has to be increased (with a file) to accommodate the disc and chimney.

4. Alternatively the precipitate may be counted only once, preferably at least 5 days after the chemical separation. The age is calculated using the appropriate line in Figure 3. If the second part of this article is performed also, it is worthwhile to measure a short portion of the absorption curve of Bi^{210} to correct the observed counting rate for absorption of the β rays by the sample, cover, and counter window.

Measurement of the Counting efficiency of a Sample

The observed counting rate, R, of a given sample of radioactive material positioned beneath the window of a counter is related to the disintegration rate of the radioactive species in the sample, A, by the expression

$$R = A \times G \times f_s \times f_a \qquad (14)$$

The factor G in this expression is called the "geometry factor" and represents the fraction of the radiations, emitted isotropically by the sample, which are emitted in the direction of the counter window. Provided they are neither deflected from their initial path nor absorbed along the way this fraction of the emitted radiations would be detected by the counter; the remaining fraction, 1-G, simply miss the counter entirely.

The factor f_s takes into consideration the effect on the observed counting rate due to scattering of the radiations along their path through matter. The materials responsible for the scattering are the sample itself, the sample mount, the housing of the counter, and even the air between the sample and the counter window. Sometimes the scattering process results in a particle being deflected into the counter from an initial path which would have caused it to miss the counter. This increases the counting rate. Sometimes the reverse is true and the counting rate is correspondingly decreased. The factor f_s is difficult to assess accurately, but so long as the sample is thin and mounted with a minimum of material around it, f_s is not very far from, but slightly greater than, unity.

The factor f_a takes into consideration the effect on the observed counting rate due to absorption of the radiations before they reach the sensitive interior of the counter. The materials which are responsible for the absorption of the radiations are the sample itself and any covering film, the air between the sample and the counter window, and the counter window itself. By determining the rate at which the radiations are absorbed by matter, called an absorption curve, it is possible to assess the factor f_a.

Usually the absorption curve is determined by interposing thin sheets of aluminum foil of known thickness between the sample and the counter window. By plotting the observed counting rate $R(t)$ as a function of the effective *total* thickness of absorber (t) (which is taken to be the sum of the thickness of the counter window, of the added aluminum absorber, of the sample cover, of the air between the sample and the counter window (1.2 mg/cm^2 per cm of air), and one-half the thickness of the sample itself, all thickness being measured by units of mg/cm^2) the data may be extrapolated to zero total absorber. This gives a counting rate $R(o)$ which is corrected for absorption effects so that the factor f_a may be eliminated from equation (14). In effect $R(o)$ is equal to R/f_a.

By measuring the absorption curve of a sample of known disintegration rate A, so as to obtain $R(o)$, the combined factors G and f_s may be obtained simply as

$$G \times f_s = \frac{R(o)}{A} \tag{15}$$

Samples of known disintegration rate may be prepared by evaporation of standard solutions which have been certified to contain a given amount of activity per unit volume. Such standard solutions are available commercially. For our present purposes, however, a suitable standard may be prepared from a uranium stock solution of known concentration. If the uranium solution has been prepared several months prior to its use the U^{238} is in secular equilibrium with its immediate radioactive descendents 24.1d Th^{234} and 1.18 m Pa^{234m} + 6.7 h Pa^{234}. Hence, for a given amount of U^{238}, the disintegration rate of each species is known. These disintegration rates for 100 mg of U^{231} are given in Table 2.

Table 2. Activities Associated with 100 mg U^{238} (Depleted Uranium)

Species	Half life	Dis/sec	Decay characteristics
U^{238}	4.51×10^9 yr	1231.8	4.2 Mev α
Th^{234}	24.10 day	1231.8	0.10 Mev β 35% (γ) 0.19 Mev β 65%
Pa^{234m}	1.18 min	1224.0	2.31 Mev β 90% 1.50 Mev β 9% (γ) 0.58 Mev β 1% (γ)
Pa^{234}	6.66 hr	7.8	1.13 Mev β 13% $\leq$0.53 Mev β 87% (γ)
U^{234}	2.48×10^5 yr	1232	4.8 Mev α

There is a rather trivial point which arises having to do with the concentration of U^{238} in the uranium stock solution used to prepare a standard source. Practically all the uranium available commercially at the present time, for example as inorganic chemical reagents, has had most of the fissionable U^{235} removed from it before it is made available for commercial use. That is, it is nearly 100% U^{238}. Natural uranium, on the other hand, is 99.3% U^{238} and 0.7% U^{235}. For any given sample of a uranium salt there might be some question as to its isotopic composition. For present purposes however, the error introduced by the uncertainty in the exact isotopic composition of the uranium is negligibly small. If the uranium reagent used in making the stock solution has been procured recently,[4] it is probably safe to assume that the secular equilibrium values are as in Table 2.

In order to prepare a standard source of known disintegration rate from the uranium stock solution, it is necessary to separate the thorium and protactinium descendants chemically and with a known efficiency of separation. It is not suitable merely to evaporate an aliquot of the solution because the resulting sample would be very bulky and it would be difficult to assess quantitatively the effects of scattering and absorption of the β radiations. The thorium and protactinium decay products of the uranium are present in the stock solution in exceedingly low concentrations so that it is necessary to employ a carrier to assist their removal from the solution. Thorium element, Th^{232}, would of course be an ideal carrier for Th^{234}, from a chemical point of view, since they are isotopic. However, thorium itself is radioactive with numerous radioactive decay products. Their presence in the counting sample would introduce complications so that thorium is not a suitable carrier for present purposes. There are, however, numerous possibilities for non-isotopic carriers for thorium. One which we shall use is the rare earth lanthanum. Both thorium and the rare earths form insoluble precipitates with F^- ion and OH^- ion. Precipitation of a rare earth ion in the presence of tracer amounts of thorium with either of these ions results in essentially quantitative coseparation of the thorium tracer. Since the thorium tracer comes to radioactive equilibrium with its Pa^{234m} daughter within a few minutes we need not be concerned whether or not protactinium is also co-separated with the rare-earth precipitate.

Apart from the question of the degree of coseparation of tracer Th^{234} with a La precipitate, there is also the matter of the efficiency with which the precipitate can be transferred to the sample mount for counting. By saving the solution and using the same vessels for a second precipitation it is possible to obtain an accurate estimate of the efficiency with which the tracer can be collected and transferred in a single separation. Suppose the collection efficiency is constant in each separation and equal to ϵ. Then the fraction of the total activity collected in the first separation is ϵ; in the second separation the fraction of the total initial activity collected is $(1 - \epsilon)\epsilon$; in the third separation it is $(1 - \epsilon)^2\epsilon$, etc. Provided ϵ is not too far from unity, e.g., >0.9, essentially all of the activity is collected in the first two separations. The efficiency of collection then can be determined by the ratio of the activities observed in the first and second separations:

$$\frac{\text{activity from 1st separation}}{\text{activity from 2nd separation}} = \frac{\epsilon}{(1 - \epsilon)\epsilon} = \frac{1}{1 - \epsilon} \tag{16}$$

In counting a sample of Th^{234} there are principally two β emitters which are detectable: Th^{234} and Pa^{234m} (Pa^{234} may not completely coseparate with Th^{234}, but most of its radiations are eliminated anyway when the absorption curve of the sample is determined). The radiations of Th^{234} are of short range while those of Pa^{234m} are much more penetrating. In order to

[4] Unfortunately, the information given on the label of the bottle is of no use in establishing the isotopic composition of the uranium.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

correct for absorption effects, and to assess the contributions to the observed counting rate by each species, an absorption curve in aluminum is determined out to about 100 mg/cm² of total absorber in increments of 10–15 mg/cm². The absorption curve, plotted on semi-log paper is observed to be flat over most of this range of thicknesses, representing the absorption of the more penetrating Pa^{234m} radiations, except for a slight rise at low total thicknesses (Th^{234} radiations). The flat portion may be extrapolated to zero total absorber to give $R(o)$ of Pa^{234m}. This value may be substituted in equation (15), along with the value of A for Pa^{234m} (Table 2) appropriate to the amount of U^{238} used. In order that the scattering factor f_s for Pa^{234m} be as nearly the same as that of Bi^{210} in the first part of the experiment, the sample of Th^{234}-Pa^{234m} should be mounted in much the same manner as the $PbSO_4$ sample. In measuring an absorption curve the aluminum absorbers should be placed close to the counter window.

The Experiment

The U^{238} stock solution is preferably made up several months in advance of its use in order to ensure that Th^{234} will be in secular equilibrium with its U^{238} parent.

For 500 ml of stock solution containing 50.0 mg U^{238}/ml, weigh out 52.729 g of $UO_2(NO_3)_2 \cdot 6H_2O$ (f.w. 502.23, assuming the uranium is 100% U^{238}). Add this to a 500-ml volumetric flask containing 4 ml of concentrated HNO_3. Fill the flask to the bottom of the neck with distilled water. Swirl the contents to dissolve the salt. Make up the volume to the mark with distilled water. Mix thoroughly, and transfer the stock solution to a clean, dry, glass-stoppered bottle. Lubricate the stopper with silicone stopcock grease. Label the bottle, including a strip of the standard warning label for radioactive materials.

Separation of Th^{234}

Using a safety pipet manipulator (propipet) (no oral pipetting!) remove two 2-ml aliquots of stock solution. Transfer these aliquots to separate, clean 15-ml centrifuge tubes. Label these tubes A and B for later identification. To each centrifuge tube add 1 ml of a 3 mg/ml stock solution of La^{3+}. Dilute the contents of both tubes to 5 ml with water. Add 1 ml of 2 M KF stock solution to each tube and swirl the contents of both to ensure complete mixing of the reagent. Allow the mixtures to stand for about 3 minutes and then centrifuge both tubes (Note 1).

With an eyedropper pipet decant the supernatant solutions from both centrifuge tubes into separate, clean centrifuge tubes. Label these tubes A or B, according to their contents, and set them aside.

Wash the precipitates of LaF_3 with 3 ml of distilled water from a wash bottle. Direct the water in a fine stream at each precipitate so as to break it up. Shake vigorously to disperse the precipitates. Centrifuge the mixtures and decant the washings with an eyedropper pipet. These washings may be discarded.

Dissolve the precipitates of LaF_3 by adding to each 1 ml of saturated H_3BO_3 solution and 2 drops of conc. HNO_3. Warm the mixture to hasten the dissolution. When the precipitates have disolved dilute the solutions to 5 ml with water. Make each solution basic by dropwise addition of conc. NH_4OH solution. (Precipitation of flocculent $La(OH)_3$ indicates when the solution is basic.) Swirl the contents of the tubes to ensure complete mixing of the reagent. Centrifuge the mixtures and decant the supernatant solutions, which may be discarded.

Add 10 drops of 1 M HCl to each centrifuge tube, allowing the acid to wash down the sides of the centrifuge tubes. Using separate, clean, eyedropper pipets transfer the contents of each tube to separate $1^1/_2$-in. squares of plastic film placed about 1 ft below a 250-W infrared lamp (Note 2). By dropwise addition of distilled water, rinse out the contents of each centrifuge tube as completely as possible, adding the washings to its respective plastic film. Call these samples A-1 and B-1. Carefully set aside the eyedropper pipet used in transferring the solutions. Evaporate the solutions to dryness with a heat lamp.

To the centrifuge tubes A and B, return the respective uranium solutions which were decanted from the LaF_3 precipitates. To each tube add dropwise approximately 1 ml of fresh La^{3+} stock solution with swirling to effect mixing of the solution. After allowing the mixtures to stand for about 3 min centrifuge the precipitates of LaF_3. Decant and discard the supernatant solutions. Wash the precipitates of LaF_3 with approximately 3 ml of distilled water. Centrifuge and decant the washings.

With the same eyedropper pipets used to transfer the solutions from the first precipitation to the plastic films likewise transfer the LaF_3 precipitates to similarly-prepared plastic films using a few drops of water to form a slurry. Rinse with successive tiny portions of water to transfer the precipitates as quantitatively as possible. Dry the slurries under a heat lamp. Call these samples A-2 and B-2.

When all samples are dry, mount the films for counting using another plastic film to cover the active deposits (Note 3). Count all samples in a counter. The ratio of observed counting rates of A-1 to A-2 and B-1 to B-2 should be 10 or greater, and the total activity collected in A-1 + A-2 should agree within a few per cent with that in B-1 + B-2. Use the counting data to compute the separation efficiencies ϵ for both aliquots according to equation (16).

Measure the absorption curves for both samples A-1 and B-1, using the same shelf as that used to count the $PbSO_4$ sample in the first experiment. Insert the aluminum absorbers close to the counter window. On semi-log paper plot the observed counting rate versus total absorber thickness (including the thickness of the covering film, counter window and air between sample and counter). At thicknesses greater than about 20 mg/cm² the absorption curve will be observed to be a straight line. Extrapolate this straight line to zero total absorber to obtain $R(o)$ (dis/sec) for both A-1 and B-1. Divide the value of $R(o)$ for each sample by the respective value of ϵ to obtain a value of $R(o)$ corrected for separation efficiency. Substitute this corrected value in equation (15) to obtain the combined factors $G \times f_s$, and average the two results. For a 2 ml aliquot of a uranium stock solution prepared as above, the value of A in equation (15) is obtained from Table 2 as 1224.0 dis/sec.

Notes

1. Before centrifugation the precipitate in the centrifuge tube is almost imperceptible.

2. Before adding the solution to the film, smear one of the filter chimneys around the bottom flange with silicone stopcock grease and press it against the plastic film. This will leave a ring of grease which will confine the liquid sample to an area equal to the area covered by the $PbSO_4$ precipitates in the first experiment.

3. If samples to be counted are mounted over holes in sample-mounting cards, tape filter papers of the same type as were used to collect the $PbSO_4$ precipitate in the first experiment over the holes in the card. Place each film on the sample card with its active deposit upside down, centering the deposit over the filter paper. Tape the film along the edge to the sample card. In this manner the film supporting the deposit acts as the cover foil. The sample is inserted with the plastic film on top and the filter paper beneath. This method of mounting gives a scattering effect which approximates that which occurs in the $PbSO_4$ precipitate. Thus to a first approximation the effect of the unknown scattering factor, f_s, in the calculation of the age of the mineral tends to cancel out.

Alkali Metal-Water Reactions

The usual experiment for illustrating the reactivity of the alkali metals with liquid water is performed by dropping a pea-sized piece of sodium into a container of water exposed to the ambient atmosphere. A typical result is seen in the right of the photograph reproduced on the cover where the sodium exhibits a brilliant display of pyrotechnics. In the left of the photograph, a piece of lithium of similar size reacts much more slowly and less violently with no splattering or evolution of light. It is instructive to inquire whether these simple experiments truly demonstrate the reactivity of the alkali metals with liquid water. An additional simple experiment can help to answer this question.

A pea-sized piece of sodium dropped into water contained in a flask continuously flushed with argon merely reacts with no combustion evident; i.e., the behavior is akin to that of lithium metal in either air or argon atmospheres. It should be clear then that the original open-air experiment with sodium does not in reality represent the typical reaction of an alkali metal with liquid water. The phenomena observed with sodium in air (*1*) are composite results of the interaction of the metal with liquid water

$$\text{Na}\,(solid,\ liquid) + x\,H_2O\,(liquid) = \text{NaOH (soln in } (x-1)H_2O) + {}^1/_2\,H_2(gas)$$

the ignition and combustion of the evolved hydrogen with atmospheric oxygen

$$H_2\,(gas) + {}^1/_2\,O_2\,(gas) = H_2O\,(gas)$$

and the ignition and combustion of the fragmented metal with atmospheric oxygen

$$2\text{Na}\,(solid,\ liquid) + {}^1/_2O_2\,(gas) = Na_2O\,(solid)$$

The flying glowing particles seen in the cover photograph for sodium clearly show the combustion of the metal in air and inasmuch as the particles are out of contact with the liquid water, the air oxidation of the metal is readily delineated as a separate occurrence. Each of the previous experiments has also been repeated with potassium metal. In air, even very small pieces of potassium ignite and burn vigorously after being thrown into water; under argon, only rapid reaction with water is observed. It is anticipated that the superoxides are formed when splattered fragments of potassium (*2*), rubidium, and cesium burn in air; lithium like sodium, yields the monoxide (*3*). In contrast to lithium, sodium in pure oxygen or in oxygen-enriched air reacts to produce the peroxide (*1*, *3*).

Reactivity and Energy Release

From the point-of-view of energy release per gram of metal reactant for the reaction

$$\text{M (alkali metal, } solid) + \infty\ H_2O\,(liquid) = \text{MOH (soln)} + {}^1/_2H_2\,(gas)$$

lithium is certainly superior to any of the other alkali metals as shown in Table 1 (*4*). Indeed, on this basis the lithium-water reaction has been considered as a most desirable propellant combination for torpedo propulsion systems (*5*, *6*). However, Table 1 also shows that the enthalpy changes per gram atom of alkali metal for the cited reaction are within about 10% of each other. The observed reactivity of a material or the violence of its reactions is frequently related to the rate at which heat is liberated during chemical combination rather than to the total amount of heat evolved over a prolonged period of time. It is of consequence then to consider those factors influencing the rate of heat evolution in alkali metal-water reactions. In this

Table 1. Heat Release Based on the Reaction:
M (solid) + ∞ H_2O (liquid) = MOH (solution) + $^1/_2H_2$ (gas)

Metal (M)	$-\Delta H^\circ_{25^\circ}$ (kcal/gram of M)	$-\Delta H^\circ_{25^\circ}$ (kcal/mole of M)
Li	17.51	121.5
Na	4.88	112.2
K	2.94	115.0
Rb	1.33	113.7
Cs	0.86	114.2

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

regard, the total amount of metal surface or the number of metal atoms exposed to the liquid water should be highly significant.

Reactivity and Numbers of Exposed Atoms

Because the enthalpy changes per mole (gram atom) of the alkali metal-water reactions are comparable, it appears that, other factors being similar (e.g., kinetic mechanisms and rate constants), the number of alkali metal atoms exposed to water at any instant will primarily control the rate of heat release. This assumes relatively little hindrance of alkali metal-water contact due to the hydrogen gas liberated.

The alkali metals have body-centered cubic structures (*7*), and the unit cell edge lengths can be readily computed (*8*) from the measured densities (*9*) (Table 2). Assuming that the metals are in the form of a unit cube (1 cm along each edge) and that planes containing

Table 2. Some Structural Parameters of the Alkali Metals and Surface Exposure

Metal (M)	Density at 20° (g/cm³)	Cube edge length of unit cell (Å)	No. of atoms exposed upon immersion in water of a 1 cm unit cube
Li	0.534	3.51	26.1×10^{14}
Na	0.968	4.29	31.6×10^{14}
K	0.86	5.33	18.2×10^{14}
Rb	1.53	5.70	18.5×10^{14}
Cs	1.87	6.18	15.7×10^{14}

equivalent numbers of atoms are uniformly exposed across each cube face (e.g., 100, 010, and 001), then with appropriate corrections for buoyancy effects due to the different densities of the metals, the number of atoms exposed to liquid water upon immersion of each metal can be approximated (Table 2). In this calculation, the number of unit cell faces (n^2) was computed for 1 cm², where $n = 1$/unit cell edge length in cm. At each intersecting point in the network of 100, 010, and 100 planes there is an alkali metal atom, and the total number of atoms in 1 cm² of these planes is $(n + 1)^2$ or for n large, $(n + 1)^2 \simeq n^2$. For a metal of density less than 1g/cm³, the total number of exposed atoms upon water immersion is approximated by $(6n^2)$ (density$_M$); for a metal of density equal to or greater than 1g/cm³, this quantity is simply $6n^2$. It is seen from Table 2 that sodium exhibits the greatest number of exposed atoms, lithium has about 20% fewer, and the other alkali metals about 40–50% fewer than sodium. Thus, this information still presents two apparent anomalies: (1) that lithium is considerably less reactive than sodium with water in air environments despite a relatively small difference in initial numbers of atoms exposed to water, and (2) that the other alkali metals are known to be considerably more reactive (*10*) than either sodium or lithium despite relatively larger unfavorable differences in the numbers of exposed atoms.

Reactivity, Fusion, and Fragmentation

Further insights into the differences in alkali metal-water interactions are to be gained by observing lithium, sodium, and potassium in reaction with liquid water at room temperature under an argon atmosphere. An irregular-shaped piece of lithium retains its original geometrical configuration when put into the water; the sodium and potassium fuse and very quickly assume symmetrical spherical shapes under the same circumstances. This is reasonable because, as seen in Table 3 (*9*), the latter two metals melt below the normal boiling point of water, whereas the water in contact with the lithium metal (melting point 180.5°C) can act as a heat sink to prevent fusion. A thermocouple embedded in a ³/₈-in. sphere of lithium immersed in room temperature

Table 3. Some Physicochemical Properties of the Alkali Metals Pertinent to Reactivity with Liquid Water

Metal (M)	Melt. temp. (°C)	ΔH_{fusion}/ Mole of M	Boil. temp., (°C)
Li	180.5	0.69	1370
Na	97.8	0.63	883
K	63.6	0.56	775
Rb	38.8	0.53	680
Cs	29.7	0.50	700

water (about 250 cm³) under air or argon indicated a maximum bulk metal temperature of only 98–103°C. Under argon, with the now molten potassium and occasionally with the molten sodium, the original spheres are seen to break up and to shatter into large numbers of much smaller fragments. This effect gives rise to a greatly increased reactivity and violence of reaction. Thus, in proceeding down the alkali metal series from lithium to cesium, the ease of fusion (decreasing melting point and heat of fusion) increases appreciably. Rubidium and cesium approach their melting points close to room temperature. Only within fairly recent times has care been taken in thermochemical studies of the alkali metal-water reactions to insure against experimental errors due to sample splattering and to secondary interaction with air (*11*).

Immersion of lithium and sodium in a slurry of ice and water exposed to air results in a pronounced diminution of activity. The sodium fuses but does not burst into flame as it does in room temperature water. The violence of the potassium-water reaction in air appears undiminished in water at 0°C. The bulk temperature of a ³/₈-in. sphere of lithium in reaction under these conditions reaches a maximum of only about 50°C, thereby indicating the effectiveness of the surrounding water as a heat sink.

It is interesting to compute the increase in total surface area starting with a cube of edge length s which undergoes a successive divisions into equal, smaller cubes. After a divisions, there are 2^a separate cubes, each of cube edge length $(1/2^a)^{1/3}s$. Thus, the total surface area is then $6(2^a)^{1/3}s^2$. Table 4 gives a tabulation of total surface area as a function of a for an initial unit cube of 1 cm edge length. From the data of Table 4, it is evident that the number of exposed atoms increases significantly with fragmentation. As a result, the observed rates of energy release and hence violence of reactions also are found to increase with ease of reactant particle division.

Under the argon atmosphere, small pieces of sodium are not as apt to fragment as are the succeeding alkali metals. Apparently, in air, rupture of sodium is easier due to the increased turbulence and exothermicity contributed by the air oxidations of the hydrogen and metal. Preliminary results in this laboratory from

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

kinetic studies of the dissolution of discrete lithium and sodium spheres in water at 25°C under argon lead to an integrated rate law of the form

$$r = r_0 - kt$$

where r is the radius in cm of the reacting metal sphere at any time t, and k is the specific reaction rate constant in cm/sec. For lithium and sodium spheres, the numerical values of k are 0.0036 and 0.0054, respectively. Thus, it seems that in a gaseous environment which is non-reactive with the metals and the evolved hydrogen, the reactivities of lithium and sodium appear rather similar despite the observed change in state for sodium. It is felt that with large pieces of lithium in restricted volumes of water the relative insolubility of lithium hydroxide may impede the reaction. As the data of Table 5 (*12*) demonstrate, lithium hydroxide manifests about one-fourth to one-fifth the molal solubility of the other alkali metal hydroxides. Based on molar volume considerations (i.e., the Pilling-Bedworth rule (*13*)), it is anticipated that suitable coatings of lithium hydroxide may have some protective effects on lithium metal, whereas the other alkali metals are not expected to be shielded by their corresponding hydroxides.

Table 4. Variation in Total Surface Area of an Array of Dividing Cubes

a, no. of divisions	Total surface area, (cm^2)	Relative total surface area
0	6.00	1.00

RbOH	17.5	15°
CsOH	25.7	25°

As noted previously, hydrogen and metal oxidations by air increase the violence of the water-initiated sequence of events. Lithium, unlike the other alkali metals (*1*, *2*, *10*, *14*), is known to be highly resistant to oxidation even at elevated temperatures in pure oxygen or in air atmospheres (*15*, *16*). It appears that the relative ease of combustibility of the alkali metals can be related to the decreasing order of their boiling points (Table 3). A similar effect is witnessed in the easy combustion of magnesium in air or oxygen as compared with aluminum (*17*), due, in part, to the greater volatility of magnesium. The usual non-ignition in air of the hydrogen evolved from lithium reacting with water is an additional moderating factor. Here one might surmise that hydrogen atoms required for sustaining a hydrogen-oxygen flame are removed close to areas of bare lithium metal to form preferentially lithium hydride which is subsequently hydrolyzed by the water. Lithium, of all the alkali metals, is known to form a stable hydride most readily (*10*).

Interestingly, lithium is known to be more susceptible to nitridation than to oxidation at moderate temperatures (*15*, *18*). Accordingly, lithium was reacted with water in nitrogen and in air atmospheres. The resulting solutions were tested for ammonia by addition of Nessler's reagent. No ammonia was found, thereby indicating that under these conditions the lithium-water reaction took complete precedence over the lithium-nitrogen reaction.

Reactions at Elevated Temperatures

Some additional experiments with alkali metals can be performed safely behind a shield using boiling water under argon. A piece of sodium injected into this environment melts as it falls through the steam-argon atmosphere and the fragmented droplets are seen to ignite, burning with a bright yellow flame throughout the volume of the flask and on the surface of the boiling water. Lithium, on the other hand, merely reacts with the boiling water without combustion. However, if as in Figure 1, the lithium is allowed to stand in the flowing steam, a white coating of material forms (LiOH, $LiOH \cdot H_2O$, and perhaps Li_2O close to the lithium surface). Within about 5 min the edges of the white coating become incandescent and liquid lithium metal flows through the cracks in the coating and starts to burn brilliantly (Fig. 2). The results reported here are interpreted in terms of the initial protective effects of the lithium hydroxide coating. As the coating becomes thicker and develops strains and cracks, it loses its protective character but continues to act as an efficient thermal insulator to raise the metal to melting and ignition temperatures by retaining the heat of the lithium metal-steam reaction. In the latter phase of the sequence of events, the reaction then tends to run away or to become "catastrophic," as occurs with the oxidation of a number of metals.

Figure 1. Initial stage of lithium-steam reaction.

Figure 2. Combustion of lithium metal in a steam atmosphere.

The present experiments are probably illustrative of alkali metal-steam flames:

$$M\ (liquid,\ gas) + H_2O\ (gas) = MOH\ (gas) + \tfrac{1}{2}H_2\ (gas)$$

Gaseous alkali metal hydroxides of various degrees of polymerization have been reported for the alkali metal hydroxides at suitably elevated temperatures (*19*, *20*) in contrast to the reactions

$$2MOH\ (solid) = M_2O\ (solid) + H_2O\ (gas)$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

at lower temperatures (*21*, *22*). It is noteworthy that hydrogen gas constitutes one of the combustion products in the alkali metal-steam flames.

Increased Reactivity of Lithium Metal Dispersions

It is, of course, well established that a very finely divided material (i.e., high total surface area per unit weight or high surface-to-volume ratio) generally evidences greatly enhanced reactivity over a like weight of the bulk material. Thus, lithium metal dispersions are quite reactive and ignite when thrown into water at room temperature in either air (*23*) or argon. The latter point was proved by placing a small amount of lithium dispersion (average particle size of 22 microns) in an argon-flushed gelatin capsule and then submerging it under water in an argon atmosphere. Once the capsule dissolved, flame was observed under the surface of the water and the hot hydrogen evolved burned in air close to the mouth of the flask.

Other Reaction Conditions

The present discussions have centered on the reactions of the alkali metals with a considerable excess of liquid water. The reactions with very limited amounts of water are of interest in the safety aspects and use of sodium and sodium-potassium alloys as heat transfer fluids to steam generators in nuclear reactors (*24*).

Abstracting Publications on Chemical Education in the Soviet Union

Current trends in Russian chemical education are of interest to specialists in the fields of chemistry, education, and Soviet studies. As part of a study of Soviet education being organized by the Soviet Studies Department of Glasgow University, work has been started in Paisley Technical College on the abstracting of material from the Russian educational journals "Khimiya v Shkole" (Chemistry in School), "Srednee Spetsial'noe Obrazovanie" (Secondary Specialized Education), and "Vestnik Vysshei Shkoly" (Higher Schools News). Much of the material—for example, review articles, biographical notes, papers on teaching methods, visual aids, apparatus and experiments, and reports of the activities of school chemical circles—corresponds fairly closely to the contents of analogous journals outside the Soviet Union, but other material reveals unique features of emphasis and approach.

Much has been written in these journals on the ways in which chemistry teaching is being brought "closer to life and production," in fulfillment of the aims of the 1958 educational reforms. Thus pupils are expected to be familiar with the Five-Year Plan figures for iron and steel production, the relative expansion planned for the chemical industry—compared with industry as a whole, and other economic data. This material links the study of chemistry with the study of "Social Science," which has recently been introduced in schools and aims to teach senior pupils the fundamentals of Marxism-Leninism. Part of the chemistry teacher's work is to prepare the way for the study of dialectic materialism and to inculcate atheism.

A characteristic feature of the Soviet educational system is the close central control over programs and curricula, textbooks, and examinations. Little if any deviation from the official curriculum is permitted. Textbooks are standardized throughout the Soviet Union, and new books are subjected to prolonged criticism in the minutest detail. Examinations are conducted on a "ticket" system: each pupil has to answer the questions printed on one, picked by chance, of a limited number of tickets whose contents are known to pupils and teachers in advance. Despite this uniformity of control, there appears to be a progressive decrease in the quality of education away from the large urban centers.

Many interesting details are revealed in the correspondence columns, where progress is reported or grievances aired, and in review articles, where details of present achievements are accompanied by exhortation to eliminate shortcomings. In an assessment of the real state of the Soviet educational system, both features have to be considered.

The Hydrated Hydronium Ion

Most students of chemistry are introduced to the concept of the hydrated proton in aqueous solution. The high charge to size ratio of the proton and its high force of attraction for water molecules is emphasized in most beginning textbooks. The monohydrated proton or hydronium ion, H_3O^+, is usually the only species discussed. It is also an important species in any discussion of the Brønsted theory of acids and bases. Recently the trihydrate of the hydronium ion, $H_3O^+ \cdot 3H_2O$ or $H_9O_4^+$, has been postulated to explain many observed properties of aqueous strong acid solutions. It is the purpose of this brief review to cite and discuss some of the evidence for the existence of this trihydrated hydronium ion.

The older evidence for the existence of the monohydrated proton, H_3O^+, is outlined as an introduction. More detailed discussions can be found in Wicke, Eigen, and Ackerman (*1*) and in Bell (*2*).

Evidence for H_3O^+

Quite conclusive evidence for the hydronium ion in solids is based on the nature of solid monohydrates of strong acids. The fact that ammonium perchlorate and perchloric acid monohydrate crystals are isomorphous and give similar X-ray patterns suggests an ionic H_3O^+ ClO_4^- structure (*3*). Nuclear magnetic resonance studies of solid $HClO_4 \cdot H_2O$, $HNO_3 \cdot H_2O$ and $H_2SO_4 \cdot H_2O$ give spectra characteristic of three equivalent protons. This suggests either a planar or pyramidal H_3O^+. Detailed consideration of observed proton-to-proton distances leads to the conclusion that the hydronium ion is a flat pyramid with H—O—H bond angles of about 115° (*4*). Infrared studies of hydrohalogen monohydrate solids show four fundamental frequencies characteristic of a pyramidal H_3O^+ ion (*5*). Estimates of the proton affinity of water based on the properties of hydrohalogen monohydrate crystals after a logical estimate of their crystal lattice energy give values (*6*, *7*) which agree with direct theoretical estimates of the proton affinity (*8*).

Direct confirmation of the presence of the hydronium ion in dilute aqueous solution of strong acids is difficult. Bell (*2*) points out that the characteristic properties of the hydronium ion will differ little from those of water which is always present in large excess, and that the rate of exchange of the proton between water molecules may be so rapid that the H_3O^+ lifetime is too short to characterize its properties.

Infrared spectra have been obtained of thin films of concentrated strong acids (*9*), which contain three of the same four bands observed for the H_3O^+ in solids (*5*).

Kinetic and electrolytic evidence for the hydronium ion in solution comes from studies of nonaqueous solvents containing small amounts of water. The reaction

$$H^+(ROH) + H_2O \rightleftharpoons ROH + H_3O^+$$

is part of a reaction scheme consistent with the rate of acid-catalyzed esterification reactions in alcohol containing small amounts of water (*10*). Other assumptions about the hydration of the proton do not fit the rate data. Liquid sulfur dioxide dissolves equimolar amounts of HBr and H_2O. Upon electrolysis one equivalent of water per equivalent of hydrogen is liberated at the cathode (*11*), which suggests that the proton migrates into the cathode compartment as H_3O^+.

The Hydrated Species $H_9O_4^+$

Over the past 10–15 years considerable experimental evidence has accumulated which can best be explained by a trihydrate of the hydronium ion, $H_3O^+ \cdot 3H_2O$ (also represented by the formulas $H_9O_4^+$ or $H^+(H_2O)_4$). Wicke, Eigen, and Ackerman (*1*) suggest the structure of this unit of proton and primary water of

hydration to be a pyramidal hydronium ion hydrogen bonded to three moles of water.

The H_3O^+ acts as a Lewis acid in reacting with three water molecules to form the $H_9O_4^+$ complex. To add a fourth water molecule to the H_3O^+ oxygen would require the complex to react as a Lewis base and if the $H_{11}O_5^+$ formed, the fourth water would probably be much less strongly bonded than the other three molecules. Thus it seems reasonable to regard the $H_3O^+ \cdot (H_2O)_3$ or $H_9O_4^+$ as the primary hydrated species.

The three hydrogen bonds are thought to be of greater than ordinary strength because the charge of the proton is directed along the three bonds rather than being distributed uniformly over the surface of a sphere as is the charge of a metallic ion. Baughan (*12*) has worked out a cycle, based on the properties of hydrogen halides, that results in a value of 283 kcal for the reaction

$$H^+(g) + \infty\, H_2O \rightarrow H_3O^+(aq)$$

This reaction is the sum of proton affinity,

$$H^+(g) + H_2O(g) \rightarrow H_3O^+(g)$$

and hydration of the gaseous hydronium ion,

$$H_3O^+(g) + \infty\, H_2O \rightarrow H_3O^+(aq)$$

The proton affinity is about 180 kcal (*6*, *7*, *8*). The difference of about 100 kcal can be assigned to the

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

hydration step. The hydration energy is made up of contributions from the three hydrogen bonds in the $H_9O_4^+$ structure and the additional hydrogen bonds of secondary water of hydration to the primary hydration shell. If the three hydrogen bonds in the $H_9O_4^+$ structure are responsible for more than 15–8 kcal of the 100 kcal hydration energy, they are stronger than conventional hydrogen bonds.

The exprimental evidence to support the existence of the $H_9O_4^+$ ion comes from the following:

Extraction studies on strong acids from water into basic solvents,
Field emission and mass spectrometry of water vapor,
The interpretation of the Hammett acidity function of strong acids,
The infrared spectra of aqueous strong acid solutions,
The activity coefficients of strong electrolytes, and
The heat capacity of aqueous solutions of strong acids.

Both the extraction studies and the field emission and mass spectrographic studies give indirect evidence of the $H_9O_4^+$ ion in aqueous solution since they indicate the existence of ions in non-aqueous liquids and in water vapor, respectively. However, if the $H_9O_4^+$ is a probable species under such conditions, it may well be a probable species in water solution. The other experimental studies were made on aqueous solution. The $H_9O_4^+$ existence depends on acceptance of the theoretical interpretation of the data obtained. Not all of the theories used have won universal acceptance but the evidence from so many diverse viewpoints seems convincing.

Extraction Studies

Fairly strong evidence for the $H_9O_4^+$ ion in non-aqueous liquids comes from the study of extraction of aqueous strong acids into basic solvents. The review of Marcus (*31*) on extraction contains a comprehensive section on the distribution of strong acids between water and basic solvents. A particularly useful study is that of Tuck and Diamond (*13*) who have extracted strong acids from water into basic solvents like dibutyl Cellosolve, diisopropyl ketone and tri-*n*-butyl phosphate. In a typical experiment, five ml of aqueous strong acid solution is extracted with five ml of the basic solvent in a graduated tube of small bore. If the total volume of the system does not change, the decrease in volume of the water layer can be interpreted as water carried into the organic layer with the acid. When perchloric acid is extracted into either dibutyl Cellosolve or diisopropyl ketone, the volume change in the water layer is linear with the amount of acid extracted and amounts to a little over four moles of water per mole of acid. If only the proton is hydrated in the water layer, this is good evidence of the $H^+(H_2O)_4$ (or $H_9O_4^+$).

When HCl, HBr, or $HClO_4$ is extracted into tri-*n*-butyl phosphate the water volume carried with the acid is linear with extracted acid to fairly high acid concentrations but amounts to only three molecules of water pr acid molecule extracted. This is still consistent with the $H_9O_4^+$ ion since water saturated tri-*n*-butyl phosphate (TBP) has one mole of water per mole TBP which results in a net exchange of only three moles of water per mole of acid during extraction.

$$[TBP(H_2O)]_{org} + [H^+(H_2O)_4 + X^-]_{aq} \rightarrow \begin{bmatrix} TBPH^+(H_2O)_4 \\ +X^- \end{bmatrix}_{org} + [H_2O]_{aq}$$

This is confirmed by the work of Baldwin, Higgins, and Soldano (*14*) who have analyzed the acid-TBP layers for water by the K. Fisher technique and find water-to-acid ratios of 4.1 and 4.6 for HCl and HBr, respectively.

Extraction of the strong acid $HFeCl_4$ into diisopropyl ether carries 4 water molecules per molecule of acid. Electrolysis and ultraviolet spectra of the organic phase indicate that all of the water is associated with the H^+ and none with the anion (*15, 16*).

Extraction studies on nitric and trichloroacetic acid into dibutyl Cellosolve (*13*) are also consistent with the $H_9O_4^+$ ion if corrections for the dissociation of these acids in the water phase are made.

Extraction studies also give evidence of the hydronium ion itself. Whitney and Diamond (*30*) finds that when perchloric acid is extracted into a less polar organic phase such as TBP diluted in some hydrocarbon only one mole of water is carried per mole of acid extracted.

Field Emission and Mass Spectrographic Studies of Water Vapor

In field emission studies of water vapor, Beckey (*32*) has observed $H_3O^+\cdot(H_2O)_n$ with n values of 0 to 10.

Knewstubb and Tickner (*33*) have studied the mass spectrometry of ions formed from the negative glow and Faraday dark space of discharges in water vapor and observed ions of the form $H_3O^+\cdot(H_2O)_n$ with $n = 0$–5. Their data indicates that the bond strength in the ion falls off sharply after $n = 3$, and that the $H_9O_4^+$ ($m/e = 73$) represents a particularly stable form.

Knewstubb and Tickner made an approximate kinetic analysis of their data on the basis of the reaction scheme

$$H_3O^+ + 2\,H_2O \rightleftarrows H_5O_2^+ + H_2O$$
$$H_5O_2^+ + 2\,H_2O \rightleftarrows H_7O_3^+ + H_2O$$
$$H_7O_3^+ + 2\,H_2O \rightleftarrows H_9O_4^+ + H_2O$$

They assumed that the measured ion currents could be taken as a measure of the ion concentration. The hydration reactions were treated as bimolecular reactions which obey first order kinetics. It was assumed that the ion bond strengths were such that thermal energy was not enough to cause an appreciable amount of reverse reaction. The rate constants were matched to data in the tail of the negative glow (2.0 to 3.5 cm from the cathode). Starting with 100% H_3O^+ in the vapor the calculation shows a fast build up of the $H_9O_4^+$ ion to better than 90% of the mixture with neither $H_5O_2^+$ or $H_7O_3^+$ being more than 20% of the mixture at any time.

Hammett Acidity Function

Bascombe and Bell (*2, 17*) have interpreted the Hammett acidity function of strong acids like HCl, HBr, $HClO_4$, and H_2SO_4 as evidence for the $H_9O_4^+$ hydrate. They point out that salt effects on the activity coefficient of a nonelectrolyte (*18*) often takes the form

$$\log f = AC$$

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

where f is the activity coefficient of the nonelectrolyte and C is the concentration of the salt. The constant A is a slope of about 0.1. Bascombe and Bell show the Hammett acidity function and water activity in strong acids solution gives such a result for the activity coefficient of the undissociated indicator base, B, if one assumes that the proton is hydrated with four molecules of water and that the activity coefficients of the hydrated proton and the indicator acid, BH^+, are essentially equal.

The Hammett acidity function is a measure of the transfer of a proton to an indicator base

$$B + H^+ \rightleftarrows BH^+$$

and is formally defined as (*19*)

$$H_0 = -\log \frac{a_{H^+} f_B}{f_{BH^+}} = pK_{BH^+} - \log \frac{C_{BH^+}}{C_B}$$

If the defining equation is written to include the proton water of hydration, with h the proton hydration number

$$B + H^+(H_2O)_h \rightleftarrows BH^+ + h\,H_2O$$

The Hammett acidity function becomes

$$H_0 = -\log \frac{a_{H^+} f_B}{a^h_{H_2O} f_{BH^+}}$$

$$= -\log C_{H^+} + h \log a_{H_2O} - \log \frac{f_B f_{H^+}}{f_{BH^+}}$$

If one can assueme $f_{H^+} = f_{BH^+}$, which is reasonable for similar size ions such as is the case with the hydrated proton and the indicator acid ion, the last term becomes $\log f_B$ and upon rearrangement

$$\log f_B = -H_0 - \log C_{H^+} + h \log a_{H_2O} = AC$$

when h is given the value 4.0, plots of ($-H^\circ$-$\log C_{H^+}$ + 4 $\log a_{H_2O}$) against C are linear and have slopes of about 0.1 for HCl, $HClO_4$, and H_2SO_4, up to molalities of about 8.0.

Another approch by Bascombe and Bell that does not require knowledge of the water activity in strong acid solution is to write the Hammett acidity function as

$$H_0 = -\log C_{H^+} + h \log C_{H_2O} - \log \frac{f_B f_{H^+}}{f^h_{H_2O} f_{BH^+}}$$

They assume that in addition to $f_{H^+} = f_{BH^+}$, that $f_B = f^h_{H_2O}$, thus the last term is zero. They substitute for C_{H^+} the acid molarity and for C_{H_2O} a function of acid molarity and molality which includes the reduction in the amount of free water by hydration. Their final equation (*2*), which assumes $h = 4$,

$$-H_0 = \log m - 4 \log (1 - 0.072\,m) + 3 \log (1 + 0.032\,m)$$

very satisfactorily predicts the observed H_0 values of HCl, HBr, $HClO_4$, and H_2SO_4 up to molalities of 8.0.

Infrared Spectra of Strong Acid Solutions

Wicke, Eigen, and Ackermann (*1*) have interpreted the infrared data of Suhrmann and Breyer (*20*) for HCl and H_2SO_4 solutions as evidence for the $H^+(H_2O)_4$ hydrated ion.

In aqueous solutions of neutral salts the water absorption is strengthened due to a partial depolymerization of the water structure. In strong acid solutions there is a structure-forming effect due to the primary hydration shell around the proton which weakens and broadens the normal water absorption bands. Sometimes this effect is obscured by a small absorption bond-strengthening effect due to the acid anion.

Suhrmann and Breyer and Wicke, Eigen, and Ackermann have calculated extinction coefficient as a function of wavelength between 1.4 and 2.3 μ for water assuming the measured extinction coefficient is the sum of a contribution from "free" water molecules plus one from hydrated molecules. Their equation is

$$K_s = hqK_b + (1 - hq)K_f$$

where K_s is the measured extinction coefficient of the solution, K_f is the extinction coefficient of free water, K_b is the extinction coefficient of bound water, h is the bound water molecules, and q is the ratio of protons to water molecules present in the solution. When h is unity, the calculated plot shows an incorrect minimum at about 1.95 μ, while the use of $h = 4$ gives a qualitative reproduction of the experimental curve.

Activity Coefficients of Concentrated Electrolytes

Glueckauf (*23*) has developed an expression for the activity coefficient of an electrolyte in concentrated solution that is in part a function of the hydration number of cation plus anion. His treatment is a refinement of the earlier work of Stokes and Robinson (*24*) in which he takes into account the effect of ionic sizes on the covolume entropy effect. His expression for the Gibbs free energy of a solution of electrolyte 1 in a solvent 2 is

$$G = n_1\mu_1^0 + n_2\mu_2^0 + G^{el} + kT\left[n_1V_1^+ \ln \frac{n_1V_1^+\bar{V}_1^+}{V} + n_1V_1^- \ln \frac{n_1V_1^-\bar{V}_1^-}{V} + n_2 \ln \frac{n_2\bar{V}_w}{V}\right]$$

The partial volumes, $\bar{V}$, are treated as concentration independent, and the chemical potential obtained by taking the derivative with respect to n_1 at constant total water. Glueckauf's final equation is

$$\log \gamma_\pm = \log \gamma^{el} + \frac{0.018\,mr(r + h - V)}{2.3\,V\,(1 + 0.018\,mr)} + \frac{h - V}{V} \log (1 + 0.018\,mr) - \frac{h}{V} \log (1 - 0.018\,mh).$$

where h is the hydration number of the electrolyte, r is the apparent molar volume divided by the molar volume of pure water, V is the sum of positive and negative ions from the electrolyte, and m is the molality.

When the equation is applied to the observed activity coefficients the values of h are 4.7, 4.7, and 4.9 for HCl, HBr, and HI, respectively. Thermodynamic considerations cannot determine hydration values of cations and anions separately but reasonable assumptions about the hydration of individual ions leads to a value of about 0.9 for the halide ion and 3.9 for the proton.

Eigen and Wicke (*21*) have developed a theory of activity coefficients of electrolytes for high concentrations. Their theory takes into account electrostatic interactions by an ingenious modification of the distribution equation used by Debye and Huckel, space requirements of the hydrated ions in the ionic atmosphere, and incomplete dissociation of the electrolyte at high concentration. The theory has been critized because of overemphasis on cloud-cloud exclusion and oversimplification of anion-cation exclusion in the cloud

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

which leads to some mathematical inconsistency (*34*, *35a*) and because the dissociation constants required to fit experimental data are not always consistent with K's from Raman spectral studies (*35b*).

The final equations of Eigen and Wicke can be fitted to the experimental activity coefficients, heats of dilution and apparent molal heat capacities of many strong electrolyte solutions. Their activity coefficient equation fits (*1*, *22*) both HCl and LiCl activity coefficient data up to 2.0 molal when they assume complete dissociation and a hydration number of 6 A for both electrolytes. This implies, but does not prove, that in this case the similar activity coefficient behavior may mean similar hydration of H^+ and Li^+ ions.

Heat Capacity of Strong Acids

The initial evidence for the trihydrated hydronium ion comes from the specific heat measurements of aqueous strong acid solutions by Wicke, Eigen, and Ackermann (*1*). Experimentally they have measured the specific heat of aqueous HCl solutions of concentrations of about 0.5, 1.0, and 2.0 molal at 8 to 10 different temperatures between 10 and 130°C. The apparent molal heat capacity of HCl was calculated, plotted against $m^{1/2}$ and extrapolated to get the apparent molal heat capacity of HCl in aqueous solution at infinite dilution at 10° intervals between 10 and 130°C. The apparent molal heat capacity at infinite dilution is separated into a contribution of H^+ and Cl^- by a technique worked out by Eigen and Wicke (*25*).

The H^+ contribution to the partial molar heat heat capacity at infinite dilution is fitted to the detailed model of Eucken (*26*) which allows hydration numbers to be estimated from the temperature dependence of apparent molal quantities. Eucken's theory assumes that the hydrated ion affects the properties of water in two ways. The first is a partial depolymerization of the water which causes a negative contribution to the apparent molal heat capacity and apparent molal volume of the solute. The second is a temperature-dependence to ion hydration. The hydration water is absorbed in two layers. The primary layer does not change with temperature and gives a further negative contribution to the apparent molal volume. A secondary hydration layer decreases with temperature and gives a positive contribution to both apparent partial molal volume and heat capacity.

The hydrated H^+ contribution to the partial molal heat capacity is fitted best with a temperature independent primary layer of four water molecules, the $H_9O_4^+$ unit, and a secondary hydration layer that decreases from 4 moles of water at 0° to 1 mole at 130°C. The hydrated H^+ contribution to the limiting value of apparent molal volume is fitted by the same hydration model.

The Eucken model (*26*) of aqueous solution pictures liquid water as an ideal solution composed of H_2O, $(H_2O)_2$, $(H_2O)_4$, and $(H_2O)_8$ species in equilibrium. The $(H_2O)_8$ species is assumed to be quite ice-like. Properties of liquid water and aqueous solution are interpreted in terms of displacement of this association equilibrium. The model has not been generally accepted and is contrary to other modern viewpoints (*34*, *36*). If the heat capacity interpretation was the only evidence of the $H_9O_4^+$ ion, its existence would probably have won little acceptance. However, when all of the available evidence from many experimental approaches is considered the $H_9O_4^+$ ion must be reckoned with as a species of considerable importance in aqueous acid solution.

Although the extraction and Hammett acidity interpretations assume no contribution of anion water of hydration, fractional increases over the 4.0 moles of water are ascribed to anion effects. In the thermodynamics approaches of activity coefficient and specific heat some arbitrary decision is made that separates cation and anion contributions. Although the anion water of hydration does complicate the interpretation the importance of the $H_9O_4^+$ ion is evident.

Other Evidence

The hydroxide ion is also hydrated. Gluckauf (*23*) gives a hydration number of 4.0 from his activity coefficient approach. Ackermann (*22*) fits the infrared data of concentrated KOH solutions with $h = 3$. Ackermann (*22*) interprets his specific heat and specific volume data on aqueous NaOH in terms of the Eucken model and gets the best fit with a primary hydration layer of 6 moles of water and the temperature dependent secondary layer decreasing from 7 moles of water at 0° to 3 moles of water at 130°C.

The three molecule hydrate of the hydronium ion is not a rigid structure that migrates through solution. There is a continuous migration of positive charge within the primary hydration unit; and when the group is properly oriented with respect to secondary waters of hydration, the charge migrates with a new water molecule coming in and an old water molecule being ejected from the primary $H_9O_4^+$ unit. Eigen (*27*) has explained protonic charge transport and fast protolytic reactions by a two step mechanism that is consistent with the $H_9O_4^+$ structure. The mechanism involves the formation of a structure with favorable orientation and the charge transfer within a hydrogen bond. Eigen believes that the first is the rate determining step in liquid water and that the latter is the rate determining step in ice.

Conway, Bockris, and Linton (*28*) discuss conductivity evidence for H_3O^+ in water organic mixtures and discuss the mechanism of proton migration in solution. Although they do not mention the $H_9O_4^+$ ion, their mechanism of proton transfer does not appear to rule out the possibility of such a unit.

The continuous realignment and exchange of water between primary and secondary waters of hydration is consistent with the kinetic viewpoint of hydration of Samoilov (*29*). He believes hydration is a matter of the time of contact between the water molecule and the ion. The water molecules around a highly hydrated ion have a longer time of contact with the ion than they do with neighboring water molecules. He postulates that the water molecules around slightly hydrated ions actually have a shorter time of contact with the ion than with neighboring water molecules.

Magnetic Stirrer

Instrument for the freshman laboratory

We have found it possible to mass produce a simple version of the magnetic stirrer. Usually the item readily available from commercial sources is unnecessarily sophisticated and costly.

The magnetic stirrer, almost indispensable for experiments in *p*H measurements, reaction rates, and distillations, is constructed entirely of new components obtained on the market at a cost of well under ten dollars and may be assembled by the students in about 20 min. The list of parts and the figure show the simplicity of this instrument. Students are encouraged to remove the snap cover in order to examine the operation of the stirrer. A degree of familiarity with the components of an instrument not only is of instructional value, but it encourages better cooperation on the part of the student to help in maintenance.

Conventional stirring bars may be used, but the student is encouraged to make his own by sealing an iron nail into glass tubing. An adequate supply of very inexpensive stirring bars is also available by cutting off a small section of a barium ferrite plastic bar. These are ideally suited to potentiometric titrations with the glass electrode because their small size greatly reduces the problem of breakage of the glass electrode.

Editor's Note: Probably readers who have had the experience of similar demands on ingenuity to replace funds will be able to contribute to a series of articles on this theme. We solicit only descriptions of instruments proven to be satisfactory by laboratory use.

Parts List

Shaded pole motor, 9 watt; Model DYAB, Barber-Coleman Co., Rockford, Illinois.	$2.89
Arc horseshoe Alnico 5 magnet, No. 5U50B, General Electric Co.	1.00
Rheostat, 25 watt, 2000 ohm; Radio Supply Outlet.	2.55
Minibox, Aluminum, 3 × 4 × 5, Radio Supply Outlet.	.77
Switch, SPST; Radio Supply Outlet.	.37
Grommet, 18-2 appliance cord, cord cap, epoxy cement, $^3/_8$-in. plywood blocks.	.35
Barium ferrite plastic rod; Edmund Scientific Co., Barrington N. J. (makes about 50 stirring bars).	1.00

Prices are for each in lots of 24 items.

Magnetic stirrer.

National Bureau of Standards Values for Physical Constants

A new, consistent set of values has been recommended by the Committee on Fundamental Constants of the National Academy of Sciences-National Research Council. The National Bureau of Standards has adopted these values for use in all NBS publications. The tables below were taken from the October, 1963 NBS Technical News Bulletin. Further information is available from the NBS office of Technical Information, Washington, D.C. 20234.

Defined values and equivalents

Meter	(m)	1 650 763.73 wavelengths in vacuo of the unperturbed transition $2p_{10} - 5d_5$ in ^{86}Kr
Kilogram	(kg)	mass of the international kilogram at Sèvres, France
Second	(s)	1/31 556 925.974 7 of the tropical year at 12^h ET, 0 January 1900
Degree Kelvin	(°K)	defined in the thermodynamic scale by assigning 273.16 °K to the triple point of water (freezing point, 273.15 °K = 0°C)
Unified atomic mass unit	(u)	1/12 the mass of an atom of the ^{12}C nuclide
Mole	(mol)	amount of substance containing the same number of atoms as 12 g of pure ^{12}C
Standard acceleration of free fall	(g_n)	9.806 65 m s^{-2}, 980.665 cm s^{-2}
Normal atmospheric pressure	(atm)	101 325 N m^{-2}, 1 013 250 dyn cm^{-2}
Thermochemical calorie	(cal_{th})	4.1840 J, 4.1840×10^7 erg
International Steam Table calorie	(cal_{IT})	4.1868 J, 4.1868×10^7 erg
Liter	(l)	0.001 000 028 m^3, 1 000.028 cm^3 (recommended by CIPM, 1950)
Inch	(in.)	0.0254 m, 2.54 cm

Clathrates: Compounds in Cages

There is a special type of inclusion compound whose properties are not well known but which are very interesting and may prove more useful than one might have anticipated. These are the clathrate compounds. About fifteen years ago H. M. Powell at Oxford University first identified these cage-like molecular compounds which he aptly named "Clathrates," from the Latin word, *clathratus*, which means enclosed behind bars (*1*). His work was anticipated by Mylius in 1886, but the earlier work went largely unnoticed. Essentially clathrates are a type of inclusion compound in which one molecule, or a framework made up of one kind of molecule, completely encloses a second. The second molecule is thereby prevented from escaping even though it is not chemically bonded to the first.

The hydroquinone cage structure, one of the first intensively studied, is frequently used to illustrate a true clathrate compound. Crystalline structure studies have shown it to have the fairly complicated pattern shown in Figure 1. The small open hexagons represent the oxygen atoms of hydroquinone molecules hydrogen-bonded together in groups of six to form a plane hexagon. The hydroquinone molecules are not shown but

Figure 1. Structure of hydroquinone clathrate. The circle in the top shows one cage (D. E. Palin and H. M. Powell, *Nature*, **156**, 335 (1945)).

the HO · · · OH axes of the molecules are shown by the sloping lines connecting the hexagons at different levels. When one cage structure is formed, simultaneously a second identical cage structure will interpenetrate it and be displaced vertically halfway between the top and the bottom of the first hexagon. In this way, hydroquinone forms a clathrate with itself, and at the same time the double interpenetrated framework will contain a cavity in which smaller molecules may be trapped. This cavity is roughly spherical and is about 4 Å in diameter.

X-ray crystal structure determinations have shown that the large hydroquinone cage in which different molecules are trapped is made up of three hydroquinone molecules for each trapped molecule. A simplified structure of the hydroquinone clathrate

Figure 2. Schematic representation of a Clathrate cage, (D. E. Palin and H. M. Powell, *J. Chem. Soc.*, **1948**, 818).

compound is shown in Figure 2. Compounds of the general formula, $3C_6H_4(OH)_2 \cdot M$ are common. The hydroquinone cage is called "the host." It has an amazing flexibility which has been compared to a lattice. This flexibility enables it to elongate in order to entertain long molecules when necessary as is shown in the simplified diagram, Figure 3. The "hinge" effect which makes the elongation possible is attributed to that portion of the structure shown in Figure 4. The elongation is noted in molecules like the hydroquinone-methyl cyanide clathrate compound whose framework is more distorted than that of any other known hydroquinone clathrate. Powell suggested that this distortion is the result of both a slight extension and a puckering of the hexagon of hydrogen bonds through which the quinol molecules are linked. Measurements of angle θ, shown in the diagram, vary when certain larger (longer) molecules are enclosed.

Inorganic as well as organic host structures are known. For example, an ammoniacal nickel cyanide solution will, on crystallization in the presence of benzene and like compounds, enclose the organic molecule.[1] As in all clathrate compounds, the cage structure is re-

[1] Editor's Note: The reader is referred to the article by V. M. Bhatnagar in This Journal 40, 646 (1963) for a more detailed discussion of this compound and its structure.

ferred to as the "host," while the entrapped atom or molecule is known as the "guest." Size, shape, location, and position of the guest at the time of crystallization, are all contributing factors to the formation or lack of formation of clathrates.

Figure 3. Schematic representation of the extension of a cage in one direction and contraction in the oppsite direction caused by the enclosure of a "long" guest molecule, (D. E. Palin and H. M. Powell, *J. Chem. Soc.*, 1948, 818).

Uses and Applications

These unusual compounds may be used to *store inert gases* (*2*). In his paper on the clathrate compounds of the inert gases, Powell showed that the volume of crystalline substance, for example of the hydroquinone-argon clathrate $3C_6H_4(OH)_2 \cdot Ar$ which would theoretically have a volume of approximately 260 ml, would contain 1 mole of argon. This same quantity, that is, 1 mole of pure argon gas, at 15°C would have a pressure of 91 atmospheres if it were to occupy the same volume when not clathrated! A more dramatic demonstration of what has occurred here is observed when we compare the volume of the clathrate compound, 260 ml, with the volume 25,100 ml which 1 mole of argon would occupy as a gas at this temperature and pressure.

It would seem that clathration of the inert gases for purposes of storage would eliminate both pressure and volume problems. It is well to mention here that when Powell prepared the inert gas clathrates he usually worked with gases under pressures up to 40 atmospheres and consequently obtained clathrates in which the cavities were not all filled with the gas atoms. The argon clathrate which he prepared has the formula $3C_6H_4(OH)_2 \cdot 0.8Ar$. The argon found in it would be equivalent to pure argon of the same quantity at a pressure of 73 atmospheres. Presumably working under higher pressures to prepare the clathrate would produce clathrates containing stoichiometrical quantities of argon, that is, with all available cavities filled. In most cases the gas may be liberated from the clathrate compound by heating it or by dissolving it. The formation of such crystalline gas-containing molecules introduces the intriguing possibility of using them to release gases in some hitherto inaccessible places and under previously disadvantageous conditions.

Figure 4. One hydroquinone molecule is shown with its oxygen-oxygen axis inclined at an angle *theta* to the 001 plane. The two hexagons of hydrogen-bonded OH groups through which this molecule is linked to the rest of the structure are drawn in, and the way in which the angle *theta* may be related to either the a or the c dimension of the unit cell is indicated. The distances marked are in angstrom units. The hinge effect is obtained by variations in the angle *theta* (H. M. Powell, *J. Chem. Soc.*, 1948, 817).

Clathrates have been used in the *separation of mixtures*. Benzene has been essentially freed of thiophene by the formation of the clathrate of benzene previously described (*3*). The benzene is preferentially trapped in the monoammine nickel(II) cyanide cage. There is no obvious manner in which the benzene molecule may be linked to the nickel cyanide complex and the structure shown has been verified by X-ray analysis methods. Since this work was first reported a method has been devised which may well become a valuable synthetic tool for the organic chemist. The clathrate of benzene-monoammine nickel(II) cyanide has been subjected to neutron irradiation and the ^{14}C benzene has been subsequently recovered for use as a labeled compound (*4*).

The *separation of isomers* by clathration (*5*) has met with notable success. In 1957, *Chemical and Engineering News* carried a report of the work being done in the research laboratories of Union Oil where Schaeffer and Dorsey had prepared over 100 different complexes which could be used to separate many chemicals which have been considered difficult to separate. They applied methods of selective clathration to various processes or production streams. At that time, tetra-(4-methylpyridino) nickel dithiocyanate was given as one compound which had been used successfully on a laboratory scale to recover *p*-xylene or *p*-cymene to make terephthalic acid. Even then, 1957, *p*-xylene production was running about 80 million pounds per year and was expected to go to 100 million pounds per year. Practical methods of separating isomers of certain organic compounds, such as *p*-xylene, were being sought. The clathration complexes are highly selective for a given isomer or isomers. A year later (1958), Union Oil research workers again reported their work on clathration going on record with the statement, "Clathrating techniques appear to have definite economic and quality advantages over other methods of purifying hard-to-separate isomers." At a more recent ACS meeting in St. Louis, Radzitsky discussed a further extension of the work of Schaeffer (*6*). His report was on the separation of hard-to-separate aromatic mixtures which is being carried out in Belgium. In this paper he described the use of new Werner complexes of the general formula $[Ni(SCN)_2$ (primary substituted benzylamine)$_4]$.

Mixtures of the inert gases have been separated. Argon has been separated from neon by adjusting the pressure conditions for clathration in such a manner that the

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

hydroquinone-argon forms but the hydroquinone-neon does not. Krypton and xenon, both form compounds with hydroquinone but xenon, being more soluble, will more readily undergo clathration than krypton. Usually a mixture of about 3 parts xenon to 1 part krypton, by volume, will be liberated from crystals which have been formed by subjection of a hydroquinone solution to equal volumes of a krypton-zenon mixture under pressure.

The *resolution of racemic mixtures* by inclusion has been extensively studied by a number of workers. The first reported resolution was that of Windaus and his co-workers (*7*). Using the solubility differences of the complexes of digitonin with *d*- and *l*- forms of α-terpineol and tetrahydro-β-naphthol, Windaus effected an almost complete resolution of *dl*-α-terpineol and *dl*-tetrahydro-β-naphthol. Powell and his co-workers alone have reported the resolution of over fifty guest molecules including alkanes, alkyl halides, alcohols, esters, ketones, ethers, and polymethylene dihalides (*8*).

Relatively recently, in a biology symposium which was held at MIT on the "Fast Fundamental Transfer Processes in Aqueous Bimolecular Systems," it was reported that they now have employed the hydrates of certain hydrocarbons, etc.—which are clathrate compounds—for examination by electron microscopy and electron diffraction as a basis for direct studies of biological systems in their native hydrated states (*9*).

In 1960, two workers at the Polish Academy of Science in Warsaw described the application of clathrate compounds in chromatography and said that these compounds afford an excellent method for the separation of isomers (*10*). They claimed the quantitative separation of ortho and other isomers of isomeric nitrophenols, nitroanilines, chloronitrobenzenes, and nitrotoluenes (*11*).

Certainly one of the most unusual uses is that devised by Chleck and Ziegler of Tracerlab. Their first report was basically a description of a new way of handling ^{85}Kr. This isotope of krypton provides a safe and useful source of radiation (*12*). Its gaseous nature is its only drawback. To overcome this obstacle a technique was developed which consisted of trapping the krypton in a three-dimensional organic crystalline cage, that is, clathrating it. According to Chleck and Ziegler, the hydroquinone-^{85}Kr clathrate which they prepared is among the safest forms of radioactivity. ^{85}Kr is virtually a pure emitter (10.3-yr, 0.67-mev β) and does not require heavy shielding for safe handling. When released from the clathrate cage, it is rapidly diluted and carried away by the surrounding atmosphere. Even if accidentally inhaled, ^{85}Kr is incapable of being metabolized or absorbed by the body. In addition, its decay product is a stable nuclide; therefore, the radiation is only that originating from krypton. Dissolution of the clathrate provides a controlled release of the gaseous krypton. The adaptability of the clathrate is further enhanced by the fact that it can be powdered into grains of salt or sugar crystal size which makes it very manageable.

Even a cursory study of clathrates and their uses will provide convincing evidence that this small segment of inclusion compounds is a versatile one. Not long ago Pauling reported studies which indicate that anesthesia may be attributed to the formation in the brain of minute hydrate crystals of the clathrate type (*13*). The hydrocarbon-rate method, recently developed, has been applied to the conversion of saline water to fresh water (*14*). The use of an α-dextrin clathrate of carbon dioxide as a baking powder had been patented (*15*). It would be difficult to imagine an area in which there are more avenues for investigation than that of the structures of molecules in biological systems. Even the degree of inclusion, whether in part, as in channel inclusion, or *in toto*, as in clathrates, or by some type of bonding, may prove to be the key to the ultimate understanding of their activities. In view of the uses to which they have already been put it would seem likely that a great deal more will be heard about clathrates in the near future (*16*).

Benzene Clathrate

A clathrate may be described as a single-phased solid consisting of two distinct components: the host and the guest. The guest is retained in closed cavities or cages provided by the crystalline structure of the host. Generally, a cage and its enclosed molecule or molecules are taken as a unit cell.

In 1897, Hofmann and Küspert (*1*) published a paper in which they stated that when benzene is added to a solution of nickel cyanide in aqueous ammonia and containing acetic acid, a precipitate of the composition $[Ni(CN)_2 \cdot NH_3 \cdot C_6H_6]$ is formed. Other examples of these molecular compounds are those formed between nickel cyanide-ammonia complex, $Ni(CN)_2 \cdot NH_3$, and molecules of aniline, benzene, phenol (*2*), and pyridine, furan, pyrrole, and thiophene (*3*). The maximum composition formula for this series of monoammine-nickel(II) cyanide clathrates is $[Ni(CN)_2 \cdot NH_3 \cdot M]$, where M is the organic molecules previously mentioned. Cambi, *et al.* (*4*) made careful magnetochemical investigations on nickel cyanide and complex derivatives. They measured the magnetic susceptibility of $[Ni(CN)_2 \cdot NH_3 \cdot C_6H_6]$ and gave the value of 11.04. The magnetic susceptibility of this clathrate was also measured by Janes (*5*) over a temperature range from 82.5 to 296°K. Although he took into account the effect of a crystal field, he found that there was no possibility of the theoretical formula for molar susceptibilities agreeing with the experimental data, because the magnetic moment of the nickel atom equal to 2.27 Bohr magnetons at 300.6°K was subnormal, i.e., smaller than the spin-only value, 2.83 Bohr magnetons. He tentatively suggested an explanation in terms of an assumption that there is a predominantly rhombic or perhaps axial crystal field, which quenches not only the orbital but also a part of the spin contribution to the magnetic moment. Janes tacitly assumed that all the nickel atoms in the compound are equivalent to one another.

A single crystal X-ray investigation was undertaken on the benzene clathrate (*6, 7*), and the large distance between the carbon atoms of benzene and the atoms of the caging material was interpreted to mean that the organic molecules are not bonded but are simply trapped in the crystal lattice. The crystal structure of this clathrate is an extended two dimensional flat network of alternating nickel and cyanide groups. In the presence of the guest component, the complex crystallizes in planar arrays of nickel cyanide with the ammonia molecules, bonded to nickel atoms, projected above and below each other. Each guest molecule is located in a cavity bound by two planes of nickel cyanide and by vertically aligned pairs of ammonia molecules (Fig. 1).

The merely space-filling part played by benzene is evidenced by the fact that other molecules of comparable volume can replace it; these are as follows (molecular volumes at 15°C in parentheses): aniline (90.5), phenol (88.8), pyridine (80.0), pyrrole (69.3), thiophene (78.5), and furan (72.0). All these compounds are included in the ammino-nickel cyanide structure to yield crystalline products of compositions corresponding to and properties almost identical with that formed by benzene [molecular volume (88.6)]. The nickel complex is, however, quite indifferent to the following larger molecules: toluene (105.6), nitrobenzene (103.6), fluoro-, chloro-, bromo-, and iodobenzene (93.8–110), toluidine (107.0), cresol (102.0), and naphthalene (111.0).

Figure 1. Cage lattice structure of benzene, ammonia, and nickel cyanide, $[Ni(CN)_2 \cdot NH_3 \cdot C_6H_6]$.

It is interesting to compare (*8*) the packing of benzene when caged in the nickel complex with that found in the solid pure hydrocarbon, which crystallizes in the orthorhombic system, with a unit cell of dimensions: a = 7.44 Å, b = 9.65 Å, and c = 6.81 Å (*9*). The flat rings are arranged in parallel layers, with the plane of the ring perpendicular to the layer planes; succeeding layers are identical but each is translated by a distance $^1/_2\ a$ relative to the neighboring plane. The closest approach of carbon atoms is between 3.8 and 3.9 Å. The similar plan for the caged structure, in which the cage imposes the higher tetragonal symmetry on the benzene, indicates that benzene molecules are closely packed, the closest approach, 3.4–3.5 Å.

The preparation of benzene clathrate has been described by Hofmann, *et al.* (*1, 2*), Palmer (*10*), and Bhatnagar and Fujiwara (*11*).

In 1955, Leicester and Bradley (*12*) reported that certain biphenyls (biphenyl, 4-amino biphenyl, and 4-hydroxy biphenyl) co-crystallize with monoammino-nickel (*11*) cyanide as solids with a characteristic

[1] Present address: Instituto di Chimica, Generale ed Inorganica, Universita di Roma, Rome, Italy.

formula of $2[Ni(NH_3)]^{2+} \cdot 2CN^-M$. However, 2-amino diphenyl and 2-2′-dihydroxy diphenyl do not form complexes under similar conditions and neither does stilbene. Baur and Schwarzenbach (*13*) synthesized a few new clathrates from double cyanides, $M\,Ni(CN)_4$, where M stands for Cu^{2+}, Cd^{2+}, or Zn^{2+}. Examples of synthesized and examined clathrates are $[Cu(NH_3)_2Ni(CN)_4 \cdot C_6H_6]$, $[Cd(NH_3)_2Ni(CN)_4 \cdot {}^3/_2C_6H_6]$, and $[Zn\,Ni(CN)_4 \cdot {}^1/_2C_6H_6]$. They are suggested to be similar to $[Ni(CN)_2 \cdot NH_3 \cdot C_6H_6]$.

A process for the recovery of benzene by selective clathration was patented by Jones and Fay (*14*). The invention related to a process and apparatus for the recovery of benzene from hydrocarbon stocks and, more particularly, to a cyclic process adapted for continuous operation for the recovery of benzene of high purity from low benzene hydrocarbon stocks, such as refinery naphthas. The process comprised continuously blending a stream of the stock with a stream of nickel cyanide-ammonia; conducting the blend to a homogenizer and homogenizing the blend to form a solid clathrate compound with benzene conducting the resultant slurry to a centrifugal separator, and centrifugally separating the solid clathrate compound from the stock; conducting the clathrate compound to a stripper and countercurrently flowing the slurry against a stream of steam and ammonia to decompose the clathrate compound into benzene and nickel cyanide-ammonia; recovering benzene, steam, and ammonia at the top of the stripper; drawing off recovered nickel cyanide-ammonia at the bottom of the stripper; and recycling the nickel cyanide-ammonia.

Aynsley, *et al.* (*15*) examined the physical properties of $[Ni(CN)_2 \cdot NH_3 \cdot C_6H_6]$, and contrary to previous assertions (*7*, *8*), they found that the benzene could be removed *in vacuo* (without removal of ammonia), slowly at room temperature and rapidly (50% in 1–3 hours) at 40–60°C. Up to at least 80% removal of benzene the decomposition was of zero order, varying in rate from sample to sample. They presumed that liberation of benzene was accompanied by a partial collapse of the lattice, which is then not wholly available for reabsorption of benzene. Discussing the two benzene frequencies at 1573 and 1166 cm^{-1}, they stated that due to relaxation of the selection rules, these frequencies appeared in liquid benzene at 1587 and 1179 cm^{-1}, but not in the benzene crystals. They expected the same restriction to be applied to benzene in the clathrate compound, and yet the band at 1166 cm^{-1} was the strongest band in the region 4000–650 cm^{-1}. Spectroscopic studies on benzene clathrate have been completed by Bhatnagar and Cole (*16*).

Kondo and Kubo (*17*) measured the magnetic susceptibilities of dicyanoamminenickel (*11*), and the clathrate compounds thereof with benzene and pyridine at room temperature and the effective magnetic moments per one nickel atom were calculated. These moments, which were approximately equal to 2.2 Bohr magnetons, were explained by the presence of equal numbers of nickel atoms having no unpaired electrons. The former have four ligands in square coordination resulting from dsp^2 hybridization, while the latter are coordinated with six ligands in octahedral coordination involving d^2sp^3 hybridization of the central nickel atoms. Drago, *et al.* (*18*) explained that since planar nickel (*11*) atoms are usually diamagnetic, it is possible that the benzene, instead of being trapped in the crystal lattice, was interacting with the nickel to produce a paramagnetic tetragonal atom. They redetermined the magnetic data and examined the infrared spectra to provide additional structural information. A structure containing trapped benzene, compatible both with the X-ray work and with the magnetic moment of 2.1 Bohr magnetons obtained in their study, was proposed. The X-ray powder diffraction pattern of decomposed benzene clathrate (*19*), electron paramagnetic resonance (*11*), and proton magnetic resonance spectra (*20*) have been described.

Evans, *et al.* (*21*) stated that if the benzene clathrate were formed from thiophene-free but otherwise impure benzene, the benzene recovered on the destruction of the compound should be quite free from the saturated hydrocarbons which are otherwise very difficult to remove. They found that by this method benzene can be obtained from impure material in good yield and of a purity as good as, if not superior to, that of samples produced by prolonged fractionation in a very efficient still, or by the tedious and wasteful process of fractional crystallization and fusion. For example, in one simple operation benzene was separated from other contaminating hydrocarbons and produced in 99.992% purity by forming the clathrate compound with nickel cyanide-ammonia and then releasing the caged benzene by dissolving the crystals.

I wish to thank Prof. N. S. Bayliss and Dr. A. R. H. Cole, University of Western Australia; Prof. R. C. Paul, Punjab University; and Council of Scientific and Industrial Research, India.

Duhem and the Gibbs-Duhem Equation

In recent issues of THIS JOURNAL, the Gibbs-Duhem equation has been the subject of numerous comments (e.g., J. CHEM. EDUC., **39**, 527 (1962); *ibid.*, **40**, 225–8 (1963)). However, the role played by Duhem has not been mentioned.

I am not as yet sure when or by whom Duhem's name was added to the equation. But it appears that Duhem was the first to use Euler's theorem explicitly to prove the Gibbs–Duhem equation. The first references appear in his book "Le Potentiel Thermodynamique"[1] which was published in 1886.[2] On pages 32–3 Duhem applies Euler's theorem to a two-component system, and on pages 141–2 he discusses the general case.

This whole subject is also given in his "Mécanique Chimique,"[3] which while not rare is usually found only in large libraries. The presentation is so clear and concise that I believe a translation of it using current notation would be interesting and informative.

Some Properties of Homogeneous Functions

It is said, with Euler, that a function $F(x_1, \ldots, x_n)$ of n variables, $x_1, \ldots, x_n$ is *homogeneous of degree m* with respect to these variables if the identity

$$F(\lambda x_1, \ldots, \lambda x_n) = \lambda^m F(x_1, \ldots, x_n)$$

holds for arbitrary $x_1, \ldots, x_n$, and λ.

Theorem I. *If a function is homogeneous of degree m with respect to the variables $x_1, \ldots, x_n$, its partial derivatives with respect to each of these variables are homogeneous functions of degree $(m - 1)$ in these same variables.*

The identities

$$F(\lambda x_1, \ldots, \lambda x_n) = \lambda^m F(x_1, \ldots, x_n)$$

$$F[\lambda(x_1 + \Delta x_1), \lambda x_2, \ldots, \lambda x_n] = \lambda^m F(x_1 + \Delta x_1, x_2, \ldots, x_n)$$

resulting from the previous definition yield

$$\frac{F[\lambda(x_1 + \Delta x_1), \lambda x_2, \ldots, \lambda x_n] - F(\lambda x_1, \lambda x_2, \ldots \lambda x_n)}{\lambda \Delta x_1} = \frac{\lambda^{m-1}[F(x_1 + \Delta x_1, x_2, \ldots, x_n) - F(x_1, x_2, \ldots, x_n)]}{\Delta x_1}$$

or, passing to the limit as Δx_1 tends toward zero

$$\frac{\partial F(\lambda x_1, \lambda x_2, \ldots, \lambda x_n)}{\partial(\lambda x_1)} = \lambda^{m-1} \frac{\partial F(x_1, x_2, \ldots, x_n)}{\partial x_1}$$

which proves the theorem.

Theorem II (Euler's Theorem). *If the function $F(x_1, \ldots, x_n)$ is homogeneous of degree m with respect to the variables $x_1, \ldots, x_n$, then one has the identity*

$$x_1 \frac{\partial F}{\partial x_1} + x_2 \frac{\partial F}{\partial x_2} + \ldots + x_n \frac{\partial F}{\partial x_n} = mF$$

By hypothesis, one has the identity

$$F(\lambda x_1, \ldots, \lambda x_n) = \lambda^m F(x, \ldots, x_n)$$

The derivatives with respect to λ of each member of this identity must also be identical with one another

$$x_1 \frac{\partial F(\lambda x_1, \ldots, \lambda x_n)}{\partial(\lambda x_1)} + \ldots + x_n \frac{\partial F(\lambda x_1, \ldots, \lambda x_n)}{\partial(\lambda x_n)} = m\lambda^{m-1} F(x_1, \ldots, x_n)$$

If the various terms of the first member are transformed by means of Theorem I and the common factor λ^{m-1} is suppressed on both sides, one finds the equality given in the theorem.

Gibbs Free Energy (Thermodynamic Potential) of a Homogeneous Solution

A homogeneous solution of fluids $1, \ldots, n$ at a constant pressure P and constant temperature T has a Gibbs free energy G which depends on the masses $m_1, \ldots, m_n$ of the fluids and on the pressure P and the temperature T:

$$G = G(m_1, \ldots, m_n, P, T)$$

At the same P and T, let us mix masses $\lambda m_1, \ldots, \lambda m_n$ of the fluids $1, \ldots, n$. We obtain a second solution, of the same nature as the preceding, but of mass λ times greater. If we neglect the forces that the various parts of a mixture exert on one another, we may attribute to the second solution a Gibbs free energy λ times greater than to the first. We will thus have for arbitrary λ

$$G(\lambda m_1, \ldots, \lambda m_n, P, T) = \lambda G(m_1, \ldots, m_n, P, T)$$

The Gibbs free energy of a homogeneous solution of n fluids is a homogeneous function of the first degree in the masses of the fluids.

Let us set

$$\frac{\partial G}{\partial m_1} = \bar{G}_1, \ldots, \frac{\partial G}{\partial m_n} = \bar{G}_n \qquad (1)$$

and apply Euler's theorem to the function G. We will have

$$G = m_1 \bar{G}_1 + \ldots + m_n \bar{G}_n \qquad (2)$$

It results from this formula that the functions $\bar{G}_1, \ldots, \bar{G}_n$ are quantities of the same type as the quotient of an energy or a work by a mass. Hence these are quantities of the same type as a potential function. We will call them *partial specific free energies of the constituents* $1, \ldots, n$ *in the solution* (thermodynamic potential functions).

In virtue of theorem I of the preceding paragraph, the functions $\bar{G}_1, \ldots, \bar{G}_n$ are homogeneous functions of degree zero in the variables $m_1, \ldots, m_n$. To each of these functions we apply Euler's theorem, and we will find the identities

$$m_1 \frac{\partial \bar{G}_1}{\partial m_1} + \ldots + m_n \frac{\partial \bar{G}_1}{\partial m_n} = 0$$

$$m_1 \frac{\partial \bar{G}_n}{\partial m_1} + \ldots + m_n \frac{\partial \bar{G}_n}{\partial m_n} = 0 \qquad (3)$$

The identities

$$\frac{\partial \bar{G}_i}{\partial m_j} = \frac{\partial \bar{G}_j}{\partial m_i}$$

This work was performed under the auspices of the U. S. Atomic Energy Commission.

[1] DUHEM, P., "Le Potentiel Thermodynamique et Ses Applications à La Mécanique Chimique et à L'Étude des Phénomènes Electriques," A. Hermann, Paris, 1886.

[2] It had actually been written in 1884 (when Duhem was 23) and submitted as a thesis at the Sorbonne. This thesis was refused through the influence of Marcelin Berthelot, who was still trying to support his erroneous maximum work principle.

[3] DUHEM, P., "Traité Elémentaire de la Mécanique Chimique Fondée sur la Thermodynamique," 4 volumes, A. Hermann, Paris, 1897–9, Vol. 3, pp. 1–4.

which result from the definition of the functions $\bar{G}_1, \ldots, \bar{G}_n$ given by equation (1), permit the substitution of equations for equations (3).

$$m_1 \frac{\partial \bar{G}_1}{\partial m_1} + \ldots + m_n \frac{\partial \bar{G}_n}{\partial m_1} = 0$$

$$m_1 \frac{\partial \bar{G}_1}{\partial m_n} + \ldots + m_n \frac{\partial \bar{G}_n}{\partial m_n} = 0$$

Duhem was a great admirer of Gibbs, was his principal champion in France, and extended a number of Gibbs' ideas. It is altogether fitting that his name be appended to the Gibbs–Duhem equation.

A classical electrostatic view of **Chemical Forces**

In the present paper, we shall attempt to review the different types of forces involved in the formation of chemical compounds, solids and liquids. In spite of the need of non-classical, quantum mechanical methods to achieve anything more accurate than the crudest qualitative calculations of the energies arising from the operation of these forces, it will be shown that, basically, they are all of a classical, electrostatic nature, and that the salient features of their operation can be understood from simple electrostatic considerations, even though these are utterly incapable of providing a satisfactory quantitative treatment.

These forces must explain the existence of the following types of matter: In the *solid state*, crystals may be classified into the following four extreme classifications, with various intermediates:

(1) Ionic crystals, consisting of an ordered lattice of ions.

(2) Molecular crystals, consisting of an orderly arrangement of neutral molecules.

(3) Extended lattice crystals, such as SiO_2, in which neither free ions, nor individual molecules can be identified.

(4) Metallic crystals, in which an orderly array of neutral atoms of one kind is held together in a manner approximating none of the other three classes.

In the *liquid state*, we must take account of:

(1) The cohesion of neutral molecules to form the disordered condensed phase.

(2) The various interactions between solvent and solute, as well as the interactions between like and dislike species in liquid mixtures.

In the *gas phase*, we note the existence of molecules, i.e., groups of atoms combined into and acting as a unit. The same problem arises for the molecules of the molecular crystal, for the entire extended lattice crystal, and for the molecules in the liquid state.

Simple Electrostatic Forces

We shall start with the interaction of two ions, of charge e_1 and e_2 at a distance r. The attractive Coulombic force between two such ions is

$$f = e_1 e_2 / r^2,$$

and depends on the distance through the inverse second power. This type of force leads to typical ionic bonds, as encountered in ionic crystals.

Figure 1. Ion-dipole interaction.

Many neutral molecules are dipoles. In the homogeneous field of an ion, such dipoles will be oriented in such a way that an attractive force results. Perfect orientation is counteracted by thermal motion, so that the attractive force varies with the degree of alignment. If the dipole (Fig. 1) is represented as consisting of two charges of magnitude $\pm e_1$ separated by a distance l, relatively small compared to the distance r from the ion of charge e_2, the force is

$$f = -(2e_1 e_2 l \cos \theta_1)/r^3$$

where θ_1 is the angle between the direction of the dipole and the ion-dipole axis. The dependence on r in this case is the inverse third power, and thus ion-dipole forces fall off more rapidly with distance than ion-ion forces. An important example of ion-dipole forces is the solvation of ions by polar molecules if no specific solvato complexes are formed.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Next, there must also be attractive forces between pairs of dipoles. The field of one dipole tends to orient the direction of another, again subject to counteracting thermal motion. If one dipole consists of two charges $\pm e_1$ separated by a distance l_1, the other of charges $\pm e_2$ separated by l_2, and the two dipoles are at a distance r (large compared to l_1 and l_2) and form angles θ_1 and θ_2 with the line joining them, (Fig. 2), the attractive force is

$$f = \frac{3e_1e_2l_1l_2}{r^4}\,[2\cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2]$$

These forces are inversely proportional to the fourth power of r, and so fall off more rapidly with increasing r than those discussed previously; they are the pre-

Figure 2. Dipole-dipole interaction.

Figure 3. Ion-induced dipole interaction.

Figure 4. Dipole-induced dipole interaction.

dominant forces responsible for intermolecular attraction, and hence for condensation to liquid and for freezing of polar substances, such as chloroform.

With the exception of forces involving quadrupoles and higher poles, the forces listed are the only ones conceivable for particles made up from a *rigid* distribution of charges. Atoms and molecules, however, are not rigid. The motions of positive nuclei and negative electrons are separate and distinct, and application of an electric field to an atom or non-polar molecule will induce a dipole moment. Thus an ion induces a dipole in any near atom or molecule, and since electronic motion is very rapid compared to atomic motion, the dipole is always in the direction of the line joining the atom or molecule, and always so oriented that the net force is attractive (Fig. 3). The magnitude of this force is

$$f = -2\alpha e_1^2/r^5$$

where α is the polarizability of the atom or molecule, e_1 the charge of the ion, and r their separation. The dependence on r is of the inverse fifth power. These ion-induced dipole forces are weaker than ion-dipole forces, but are important in the solvation of ions by non-polar molecules.

Just as the electrical field of an ion is capable of inducing a dipole in a non-polar molecule, the field of a permanent dipole has a similar effect. Again, the orientation of the induced dipole is such that it points toward the permanent dipole, (Fig. 4), and leads to an attractive force, which is given by

$$f = -\frac{3\alpha e_1^2 l_1^2}{r^7}\,(3\cos^2\theta_1 + 1)$$

where the permanent dipole consists of charge $\pm e_1$ separated by a distance l_1 and inclined at an angle θ_1 to the line joining it to the atom or molecule of polarizability α at a distance r.

Since the electrons in atoms or molecules are in a constant motion the angular distribution of which is random, any atom or molecule has associated with it a dipole of constantly changing magnitude and direction. Maybe the easiest way of visualizing such a dipole is by considering the motion of one electron in the field of a singly charged nucleus, i.e., the hydrogen atom. It is immediately apparent that at any one moment this pair of particles represents a dipole moment—provided we make the classical assumption that at a given moment the electron may be localized at a particular point. Visualization of a momentary dipole for a many-electron atom is less straightforward; but there is no reason that, momentarily, the electrons should be symmetrically distributed about the nucleus—although in the time average they are—and hence atoms represent momentary dipoles. The same is true of molecules.

These changing dipoles of neighboring molecules are randomly oriented, and thus lead to no net force. But the existence of these *temporary* dipoles leads to the induction of added induced dipoles in neighboring molecules, and these always give an attractive force. These forces are the van der Waals or London dispersion forces, and as such are responsible, among other things, for the condensation of nonpolar substances, e.g., rare gases and methane to liquids and solids.

Figure 5. Quadrupoles.

In addition to the various forces listed, it must be realized that all molecules represent quadrupoles (and higher electric poles); two kinds of quadrupoles which are of different orders of magnitude should be distinguished. If bonds in a molecule are polar and

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

the lack of dipole moment in the molecule, from the molecular symmetry (CCl_4, CO_2), rather large quadrupole moments can be expected (Fig. 5a). In molecules without polar bonds (e.g., homonuclear diatomic molecules), however, the high concentration of electrons in the bond leads to a quadrupole moment of smaller magnitude (Fig. 5b). The Coulombic forces between quadrupoles on the one hand, and ions, dipoles, and quadrupoles on the other can readily be calculated. Their magnitude, however, is generally so small that they make little or no contribution.

Finally, it must be pointed out that the equations given above break down when the separation of charges becomes of the same order of magnitude as the separation of particles. These equations give, however, an excellent qualitative picture of the forces involved and may well be used for calculations of orders of magnitude.

We have thus accounted for the forces involved in four items of our original listing: the ionic forces of an ionic crystal, the van der Waals and London forces of the molecular crystal, the cohesive forces of liquids, and the forces leading to solvation of ions and molecules. The interactions leading to molecule formation and to the formation of extended lattices are covalent bonding forces, and the metallic crystal may be envisaged in terms of the same covalent bonding forces, or by other quantum mechanical models, all of which will be discussed in the next section.

Covalent Bonds

Aside from this array of direct electrostatic interactions between ions, dipoles, induced dipoles, and higher poles, we must consider covalent or electron bond forces. Even though these forces are often specifically distinguished from electrostatic forces, we will show that they also are of electrostatic origin. However, their understanding requires the methods of quantum mechanics.

Quantum mechanics can be considered as based on the Schrödinger equation

$$H\Psi = W\Psi$$

as a fundamental postulate, which cannot be proved *a priori*, but which is justified *a posteriori* by comparison of the results derived with experiments. In this equation H is the *Hamiltonian operator;* Ψ, a function of all the space and spin coordinates of all particles under consideration, and of time, is called a *wave function*, or *eigenfunction;* and W is a differential operator involving time. For most molecular problems it is practical to remove from Ψ a factor containing the time dependence, in which case W simply becomes the total energy of the system. Without going into detail, we must take a closer look at the Hamiltonian operator H. It consists of two parts: the first of these involves the partial differentiation of Ψ with respect to space coordinates, and represents the *kinetic energy* of the particles.

The second part of the Hamiltonian operator represents *potential energy* of the particles. When written down completely, it is an infinite series, involving interaction terms for charges, dipoles, multipoles, both of electrostatic and magnetic nature. It is, however, a common experience of people working in quantum mechanics that, for calculation of energy quantities, including the binding energy of molecules, only the terms involving attraction and repulsion of charged particles are of importance. Hence a single term e_ie_j/r^2, representing the mutual electrostatic interaction of the particles i and j, is needed for each pair of particles. Additional terms, of course, must be included for any externally applied forces, but such forces are rarely of concern in discussions of bond energies.

In the treatment of molecules, the particles which are considered are the individual electrons (particularly valence electrons) and the nuclei (or kernels, i.e., nuclei including inner shells of electrons). In this case, the second part of the Hamiltonian represents the electrostatic attraction between electrons and nuclei (or kernels), and the electrostatic repulsions between pairs of electrons and between pairs of nuclei (or kernels).

Unfortunately it is impossible to solve the Schrödinger equation rigorously, for more than two particles, and consequently approximation methods must be used. Two main methods are available, and if carried to completion, give identical results. Usually however, it is impractical to carry either method to completion, and very approximate results are generally accepted. The two methods are the valence bond (VB) method (resonance method) due largely to Heitler, London, Slater, and Pauling, and the molecular orbital (MO) method, developed mostly by Hund, Mulliken, and Hückel.

Both methods are, in principle, capable of explaining the existence of molecules and chemical bonds. In practice, the calculations are so cumbersome that few treatments even approaching completeness have been reported save for some of the simplest molecules—mostly diatomic ones, linear triatomic ones, and hydrides. However, these calculations indicate that the existence of molecules, and of chemical bonds such as are responsible for extended lattices, are tractable by arguments—although quatum mechanical ones—based only on the electrostatic interactions of nuclei and electrons.

The same types of calculations can be applied to metallic crystals, although they become extremely cumbersome, involving, for example, the resonance of a single covalent bond between large numbers of nearest neighbors. A more effective argument is the treatment of the metal as a network of positive nuclei (or kernels) imbedded in a sea of electrons. This model can also be treated rather successfully quantum mechanically if only the electrostatic terms are included in the potential energy portion of the Hamiltonian operator.

Prout's Chemical Bridgewater Treatise

The argument for the existence of God from the "wonder of His works," forms the province of natural theology. This was a subject of great popularity during the eighteenth and early nineteenth centuries (*1*), and one which seemed quite valid until Darwin's theory of evolution demolished it in its original form. Until then, no clergyman felt himself fully equipped unless he had a fair knowledge of natural history or natural science. In the seventeenth century, both Boyle and Newton had stressed that religion and science were not in conflict, and that the "Mechanical World Picture," far from leading to atheism, actually supported the existence of a Designer. "And thus much concerning God, to discourse of whom from the appearances of things, does certainly belong to Natural Philosophy," Newton had written (*2*). When Boyle left a sum of £50 at his death for the delivery of eight annual sermons—the Boyle Lectures—for the refutation of "notorious infidels," Richard Bentley, the first lecturer, drew examples from Newton's mechanics to prove the existence of a Deity.

The number of books written on natural theology is enormous, but they are all well epitomized by the most famous treatise on the subject, William Paley's immensely successful "Natural Theology" of 1803. It has been said of Paley's arguments that

> . . . he paid far too much attention to finding examples of apparent design in Nature, and not enough to the analogical inference that design in Nature (necessarily) implies the existence of a designer (*3*).

Bridgewater Treatises

This criticism also applies to the Bridgewater Treatises, "that strange and deadly series (*4*)" which appeared during the third decade of the last century. These eight treatises were sponsored by the will, dated 1825, of the eighth and final Earl of Bridgewater, Francis Henry Egerton, who died in 1829. Son of a bishop, Egerton was a clergyman who "assiduously neglected his parish (*4*)" for literary and historical scholarship. Now a scientist, he was nevertheless made a Fellow of the Royal Society in the days when the Royal Society was largely a gentlemen's dining club rather than a scientific institution. The Earl was an extremely rich man, for besides his legacy to the Royal Society, he also left £12,000 to the British Museum for the provision of his Egerton manuscripts. He was also one of England's great eccentrics.

The terms of the will must have provided a problem to the Royal Society's president, Davies Gilbert, who himself did not live to see the publication of the treatises. Eight thousand pounds had been invested in Bank Annuities stock and held at the disposal of Gilbert to be paid to the person or persons nominated by him. The person or persons appointed, were required to

> . . . write, print and publish, 1000 copies of a work on the Power, Wisdom and Goodness of God, as manifested in the Creation; illustrating such work by all reasonable arguments, as for instance the variety and formation of God's creatures in the animal, vegetable and mineral kingdoms; the effect of digestion, and thereby of conversion; the construction of the hand of man, and an infinite variety of other arguments (*5*).

Gilbert thought the task was too much for one man, and perhaps that £8000 was too great a windfall; hence, alone, or by consultation, he decided that the legacy should be broken down into eight lots of £1000—a decision that was harshly criticized by the "Edinburgh Review" and "Athenaeum." At this stage, Gilbert allocated the task of choosing the eight authors to the Royal Society Secretary, Peter Roget. Roget, who is widely known as the author of "Roget's Thesaurus," with the aid of the Archbishop of Canterbury and the Bishop of London, had by July, 1830 obtained the agreement of eight authors. Through 1833–6 the treatises appeared, and went through further editions well into Victoria's reign.

William Prout, Physician and Chemist

The eighth Bridgewater Treatise was "Chemistry, Meteorology and the Function of Digestion (*5*)" by the chemist and physician, William Prout, who is best known as the foremost nineteenth century exponent of the speculation that all the chemical elements possess atomic weights that are integral multiples of the atomic weight of hydrogen (*6*). Prout was born in 1785 at Horton in Gloucestershire. A country lad, he received a negligible education until, at the age of 17, he suddenly became aware of his own ignorance. Ambitiously, he inserted an advertisement in a local paper asking advice on his prospects for further education! A reply came from the Rev. Thomas Jones who ran a classical seminary near Bristol. Prout, who was later to name his youngest son Thomas Jones Prout, spent two happy years with Jones who interested Prout in the chemistry of Lavoisier and Davy and urged him to become a doctor. Prout entered Edinburgh University in 1808, and was graduated as an MD in 1811 with an uninspired dissertation on fevers. During his medical course he boarded with Alexander Adam, the Rector of Edinburgh High School, whose daughter, Agnes, he married in 1814. There were six children and the boys reflected Prout's new social status by becoming respectively soldier, lawyer, surgeon, and Oxford don.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

After receiving the best medical education possible to obtain in Britain, Prout came to London, where he set up a medical practice and soon established a reputation for work on what was then termed "Animal Chemistry"—in fact biochemistry. Over the years, with improved apparatus and techniques for organic analysis, he analyzed a tremendous variety of substances, prepared pure urea, and wrote a useful textbook of urine pathology which established him as a specialist on urinary and digestive disorders (*7*). In 1823, he analyzed the gastric juice and solved the old problem as to the nature of its vital ingredient, hydrochloric acid. From there he went on to consider the biochemistry of digestion and assimilation, in which his views foreshadowed those of Liebig.

Nevertheless, despite a list of impressive achievements, we find that, apart from *the* hypothesis, neglect of Prout's chemical and pathological work had already set in long before his death in 1850. There are two reasons for this. First, his active scientific career was essentially finished by 1834. Thereafter he devoted himself entirely to his medical practice and the revision of his books, while severe deafness prompted him to avoid scientific company. Second, in direct consequence, Prout was unable to keep abreast with the rapid scientific developments in chemistry and physiology, so that although much of his early research precursed that of Liebig and his school, in the main, Prout found himself overshadowed by the great achievements of the 1830's and 1840's. One aspect of this was his refusal to use chemical formulas and equations. The Royal Society, of which he was a Copley medallist, ignored his death, as did the infant Chemical Society; only the physicians remembered him and paid him handsome tribute in their chief medical journals. For the general public he was just an author of a Bridgewater Treatise.

There were three editions of Prout's treatise during his lifetime, and a posthumous fourth edition which appeared in 1855. John Tyndall, the agnostic physicist was asked to edit this final edition. His reaction was as might have been expected (*8*).

> . . . I should have thought more highly of Dr. Prout had I not read his book. Certainly if no better Deity than this can be purchased for the £8000 of the Earl of Bridgewater, it is a dear bargain. It is very evident that Dr. Prout would never have written such a book through the spontaneous promptings of his own spirit; it was written for money, and lacks even common scientific depth, not to speak of religious inspiration.

Tyndall had read his Paley in 1849, but not from any religious motive! He is quite wrong to say that the book lacked scientific depth; but as for the financial sneer (a common criticism that all the Bridgewater authors faced), although it would be rash to doubt Prout's sincerity, it might be pointed out that he had a large family, with children at public school, and later Oxford. We also know that he never spared any expense over apparatus. For instance, his barometer, which he designed himself, cost "an incredible sum of money." Indeed, the Royal Society, whose own standard barometer was modeled on that of Prout's and built under his supervision, haggled over the bill when it came to be paid.

The theological argument of the "Chemistry, Meteorology and the Function of Digestion" followed the pattern of finding examples of utility and design in both the inorganic and organic kingdoms, and by cumulative effort, argued that there is a unity of design and purpose which must spring from a beneficent and superior Being.

Divided into three books, Prout was equipped to discuss all three subjects, although in fact, the "Meteorology" is pedestrian and derivative. The third book on the biochemistry of digestion, was much in advance of contemporary knowledge, and it still reads well today, despite its vitalism and ignorance of pepsin and glycogen. It was in this section that Prout repeated his classification of foodstuffs into the three categories of saccharinous (carbohydrates), oleaginous (fats), and albuminous (proteins) (*9*), and suggested chemical mechanisms whereby these foodstuffs were ultimately converted into blood. A pioneer nutritionist, he always stressed the importance of a balanced diet, of which milk was "the great alimentary prototype." To copy this prototype was the whole art of good cookery.

Prout's Chemistry

The "Chemistry" is of considerable interest. Apart from a few historians of science, who know today that the word *convection* was first coined by Prout in this book, or that Prout clearly stated and accepted long before the majority of chemists what we today recognize as Avogadro's law (*10*)? His attitude toward the atomic theory of Dalton is best summarized in a letter he wrote to his friend Charles Daubeny in 1831.

> . . . There is no one can have a greater respect for Mr. Dalton, and all that he has done, than myself, and I am a firm believer in his principles *as far as they go*, because I believe them to be founded in truth (*11*).

However, Prout did not believe they contained "*all* the truth, and that consequently in *their present state* they are inadequate to explain the operations of nature." What were these inadequacies?

Dalton's classical atomic theory had assumed (*12*) that matter was composed of atoms that were qualitatively and quantitatively identical for the same element, or different for unlike elements. Since he had no chemical means for determining the molecular formulas of compounds, he simply assumed that compounds were binary, unless there were reasons to suppose otherwise. Thus, using Berzelian nomenclature, of the possible formulas of water, HO, H_2O, HO_2, H_3O, etc., Dalton chose the simplest, HO. He had then shown how this assumption could be fruitfully used to assign an atomic weight to every element, if the results of quantitative analysis were known. Thus, if water was HO, then the atomic weight of oxygen was 8 (H = 1). Dalton's *atomic* weights are of course *equivalent* weights.

The rule of simplicity was quite unsatisfactory, and the history of nineteenth century atomism may be read as a long search for reliable molecular formulas. This search was only completed by Cannizzaro in 1858, yet some minds, including that of Prout's, had seen the answer to the difficulty very much earlier, although their suggestions went by unnoticed or unapproved.

In the Bridgewater Treatise, Prout discussed Gay Lussac's law of combining volumes of gases, and Gay Lussac's and Dalton's law of gaseous expansion. He

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

went on to remark that these were "very striking facts which apparently lead to the additional conclusion that —all perfectly gaseous bodies under the same pressure and temperature contain the same number of self-repulsive molecules." His argument was:

> ... If different gaseous bodies contained unequal numbers of self-repulsive molecules, the molecules of those gases which contain the least number, must exert the greatest self-repulsive power; in other words, the expansive energies of the molecules of a gas must increase as their number diminishes; and not only so, but the expansive energy must increase, neither more nor less, but exactly as the number of molecules diminishes. Such a conclusion would be obviously false; for if we imagine an extreme case, and suppose the number of self-repulsive molecules in a given volume of gas to be reduced to a few, or to one for instance, this single molecule must be supposed to exert a self-repulsive power, equal to the self-repulsive power exerted by myriads of molecules under ordinary circumstances.

It is not known when Prout arrived at Avogadro's law, but it must have been prior to 1815. We have his word that he arrived at the law independently of Avogadro, or the versions of Ampere and Dumas.

Dalton himself had thought of the hypothesis of equal volumes, but only to immediately reject it, since he identified what Prout was to call the *molecule* with the *atom*. To accept it was to destroy his axiom concerning the indestructibility of the atom. Thus,

1 vol. H (n atoms per vol.) + 1 vol. Cl (n atoms per vol.) → 2 vols. HCl ($n/2$ atoms per vol.)

In order to save the hypothesis, the atoms of the reactants would have to be "split" into two parts—a step Dalton was not prepared to make, so he abandoned the hypothesis. The alternative was to say that the "Dalton atom" was not *the* atom, but a particle, or molecule, or physical atom, composed from *at least* two indivisible chemical atoms.

However, Dalton and the majority of chemists refused to take this step, and it was left to Avogadro, Ampere, Prout, and later Dumas and Gaudin to point out the way for a more reliable set of criteria for the establishment of atomic weights.

Prout argued that the production of water proceeded according to, at least,

$$2H_2 + O_2 \rightarrow 2H_2O$$

and consequently the atomic weight of oxygen was 16 and not 8, or a volume of oxygen weighed 16 times an equal volume of hydrogen. He concluded,

> ... the weights of the self-repulsive molecules of all bodies are as the specific gravities (i.e., relative densities) of these bodies in the gaseous state; or bear certain simple ratios to these specific gravities.

Thus,

$$\text{Relative density of gas } x \text{ (H = 1)} = \frac{\text{Mol. wt. of } x}{\text{Mol. wt. of H}}$$

whence we derive the familiar equation, "molecular weight is twice relative density." Prout had stated this equation in the form,

$$\underset{(\text{air} = 1)}{\text{specific gravity of gas } x} = \left(\frac{\text{sp gr of oxygen}}{2}\right) \times \underset{(0 = 10)}{\text{at. wt. of } x}$$

in his famous anonymous paper of 1815, "On the Relation of the Specific Gravities of Bodies in their Gaseous State and the Weights of their Atoms (*13*)."

In this paper he incidentally noticed that the calculated relative densities were integral numbers. This led him to speculate that all the elements were condensed from hydrogen, or something simpler than hydrogen; and the abandonment of another Daltonian axiom—that there were as many atomic species as chemical elements. It has often been noticed that Prout's hypothesis was an explicit statement of hints and speculations dropped by Thomson and Davy, and that he was directly influenced by these chemists (*14*). However, we can go further and now suggest that the Bridgewater Treatise shows that Prout's acceptance of the "Avogadro law" prepared his mind to *split* the Daltonian atom whenever necessary. Hence, he found no difficulty in moving to the position where *all the elements* were polymers of the hydrogen atom or some simpler species.

In fact, having derived the law of Avogadro and having perceived its entailments, Prout saw no good reason not to permit the existence of molecular aggregates like (H_2O), $(H_2O)_3$, $(H_2O)_6$, etc., and series of combining weights, 3, 6, 9, 12, etc. Unlike Dalton and Avogadro, Prout never thought it necessary to build a simplicity rule into his atomic theory. Of the possible molecular equations satisfying Gay Lussac's and Avogadro's law,

$$2H_2 + O_2 \rightarrow 2H_2O$$
$$2H_3 + O_2 \rightarrow 2H_3O$$
$$2H_4 + O_4 \rightarrow 2H_4O_2$$
$$\text{etc.}$$

Avogadro had chosen the simplest consistent one. Indeed it was a source of criticism leveled against Avogadro: Why should molecules cease building at O_2, H_2, etc.? Why not H_3, H_4, O_4, etc.? Prout thought it likely that such molecules did exist.

> ... The molecule of water, on entering into combination, is often found to be divided into two, or three (perhaps more) parts. Now as we cannot admit the division of the ultimate molecule, or atom; we must of course conclude, that the molecules of oxygen and of hydrogen, are much more compounded ... and must each of them contain at least, three components, or submolecules. Hence the molecule of water will consist of at least nine component submolecules (viz. three of oxygen, and six of hydrogen) which we may suppose to be associated, in the first place, the hydrogen with the oxygen chemically; and afterwards the three submolecules of water with one another cohesively, so as to constitute one spherical molecule.

As a book of apologetics, probably Prout's Bridgewater Treatise had little scientific influence. His unitary hypothesis was already widely known, and in any case it was not figured prominently in the treatise. His views on atoms and molecules, which roughly coincided with the more publicized suggestions of Dumas in France, were discussed favorably by Daubeny in the second edition of his "Introduction to the Atomic Theory (*11*)." However, this did not appear until 1850, by which time Avogadro's law had already received its reappraisal from Dumas's pupils Laurent and Gerhardt, and was to be supported by Williamson after his return from France in the same year.

If we can find no use made of Prout's ideas, this need not in any way diminish the interest of his chemical Bridgewater Treatise to us, for it enables us to determine the attitude of a chemist who was prepared to think out, and when necessary reject, the basic assumptions of Dalton's atomic theory, rather than

follow the majority of chemists who tended to take a phenomenalist or nonrealist attitude toward the atom. As Daubeny wrote: Prout showed

> . . . a thorough mastery of the details of his subject, but also much ingenuity in unraveling the mysteries which beset us when we attempt to speculate on the intimate constitution of matter.

Who Discovered Galvanism?

Luigi Galvani, after whom galvanism is named, was an Italian biologist who was studying the effect of an electric current on the nerves of skinned frog legs. The electricity caused the muscles to undergo convulsions and the leg to twitch. According to encyclopedias, legend has it that Galvani's wife, nee Lucia Galeazzi, daughter of a teacher of anatomy under whom Galvani studied, was a woman of superior intelligence. One day as she was preparing frog legs for her husband's experiments she noticed that when her scalpel touched the metal of the machine on the table and was simultaneously in contact with the nerve of the frog leg, the leg twitched just as when an electric current was imposed. Galvani, in his writings, states that one of his assistants made this observation; and most encyclopedias seem to assume that Galvani's wife was that assistant.

Over the years as I encountered many interesting aspects of galvanism relating to the corrosion inside food cans, I developed a real admiration for Galvani's wife as a result of her observation, and felt that she should be given credit for the discovery of galvanism rather than her husband. But this admiration received a severe shock from a lecture entitled "The Guide of Life" by C. J. Ducasse, professor of philosophy at Brown University, as published in the January 1958 issue of Phi Beta Kappa's *Key Reporter*. According to Ducasse's version, Galvani's wife was a consumptive, and her physician prescribed broth from frog legs to strengthen her. One day as Galvani stood on his balcony which had an iron railing to prepare frog legs for his wife's broth, he hung the prepared legs on the railing with copper hooks. He observed the same muscular contraction and twitching that an electric current caused. This version of the discovery, I find, has received ridicule in the literature as being an old wives' tale: If Galvani were cooking for his wife, he would more likely be doing it in the kitchen rather than in his laboratory or on his balcony. Moreover, why should he use copper hooks to hang the legs? To me, it seems strange that a physician, whom one would assume to be of a high order, would believe that the tremendous strength of frog legs would be an inherent property of the broth made from them. After all, Galvani was a biologist, and as such it is doubtful that he would harbor such a notion.

Neither Professor Ducasse nor I have been able to find conclusive evidence for the correctness of either of these stories. Recently I have checked through translations of Galvani's original publications dealing with this theme.

There is no doubt that Galvani studied the bimetallic effect on the nerves of many dead animals. He noted the effect of electricity produced by friction and electricity from a Leyden jar. He studied the effect of electricity from lightning at various distances and correlated this effect with the peals of thunder at great distances. Of most significance was his study of what has been termed a "marine torpedo," an electric animal, perhaps what we know as an electric eel. After finding that many sources of electricity applied to the nerves of dead animals caused muscular contraction, he found that the electricity from the marine torpedo had the same effect. As a biologist, he was not diverted from his contention that he was observing animal electricity, "De Viribus Electricitatis." When there was no lightning and he hung frog legs with copper hooks on his iron railings, he felt that he had discovered atmospheric electricity.

Probably his greatest achievement, as far as galvanism is concerned, was the arousal of interest in Alessandro Volta. When Galvani's work first came to Volta's attention, the latter was inclined to accept Galvani's idea that the electricity involved was animal electricity. He interpreted it as an upset in the amount of electricity in the muscle and in the nerve; the two metals served to complete the circuit and restore the balance. But as Volta experimented himself, he soon changed his mind. He first observed that when he placed a piece of tinfoil on his tongue in contact with a silver coin, there developed what he called a sourness. When he made his eye a part of the circuit between two metals, it created a sensation of light just as a blow on the eye does. Volta was soon convinced that the two metals were responsible for the electricity.

Then began the heated argument that is said to have led to the discovery of useful electricity. But the controversy was not between Galvani and Volta as is usually stated. Rather it was between Volta and Galvani's nephew, Giovanni Aldini, professor of physics at Bologna University. Galvani is reported to have tried to answer Volta in only one publication. He seems never to have realized that the electricity involving two metals results from a change in one or both to produce electric energy. Galvani reported that an assistant first noted the bimetallic effect on frog legs, though there seems to be no record of the identity of the assistant. I am quite willing to assume that the assistant was his wife.

Terpenes to Platinum: The Chemical Career of Lev Aleksandrovich Chugaev

Virtually every college freshman who is exposed to a course in qualitative analysis is familiar with the scarlet precipitate formed by the reaction of nickel(II) ion with dimethylglyoxime, the first organic spot test reagent used to detect a metal ion. Yet, it is probable that only chemists concerned with coordination compounds are aware that this analytically important reaction (Chugaev's reaction) was but one of many discoveries made in varied fields of chemistry by Lev Aleksandrovich Chugaev.

Chugaev (1873–1922) was the foremost figure and undisputed leader of a group of Russian chemists who systematically explored the coordination compounds of platinum and its congeners. His versatility rivaled that of Mendeleev, his predecessor in the chair of inorganic chemistry at the University of St. Petersburg. His scientific contributions ranged through bacteriology, biochemistry, organic chemistry—especially that of the terpenes, optical rotatory dispersion, coordination compounds, and analytical chemistry. He was also founder and first director of Russia's world-famed Platinum Institute.

In view of the magnitude of Chugaev's contributions it is indeed astonishing that the only biographical data available in English is in a short 3-page obituary (*1*), which appeared shortly after his premature death at the age of 49. This prolific worker, for whom chemistry was paramount and for whom personal life was almost non-existent, produced more than a hundred articles during his short scientific career. The biographical data in the present paper are taken largely from a tribute presented by Chugaev's student and co-worker, the late V. V. Lebedinskiĭ, on November 13, 1944, in Moscow at the Third Conclave on the Chemistry of Complex Compounds (*2*).

Life

Lev Aleksandrovich Chugaev, the son of a physics teacher, was born on October 4, 1873, in Moscow and received his primary education in a military academy.[2] As a student in the Natural Sciences section of Moskovskiĭ Universitet (Moscow University), he studied inorganic chemistry under I. A. Kablukov and organic chemistry under N. D. Zelinskiĭ, with whom he published his first chemical paper in 1895. Following his graduation from the University in that year, he was appointed *Adiunkt* (assistant) in the Chemical Laboratory of the Bacteriological Institute. In 1903, he successfully defended his dissertation "Issledovanie v Oblasti Terpenov i Kamfary" (Research in the Area of Terpenes in Camphor) and was granted the degree *Magistr Khimii* (Master of Chemistry). From 1904 to 1908, he was Professor at the Moskovskoe Tekhnicheskoe Uchilishche (Moscow Technical High School).

Lev Aleksandrovich Chugaev lecturing on qualitative analysis.

Presented in part before the Division of the History of Chemistry at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

[1] Address for the academic year, 1963–4, Anorganisch-Chemisches Institut der Universität Zürich, Rämistrasse 76, Zürich, Schweiz.

[2] The author is indebted to Dr. Louis Schmerling, Universal Oil Products Company, for the information that Chugaev was a maternal half-brother of V. N. Ipatieff. For this, and other personal reminiscences about Chugaev, see "The Life of a Chemist: Memoirs of Vladimir N. Ipatieff," edited by X. J. Eudin, H. D. Fisher, and H. H. Fisher, Stanford University Press, 1946.

In 1906, he was awarded the degree *Doktor Khimicheskikh Nauk* (Doctor of Chemical Sciences) for the successful defense of his dissertation "Issledovanie v Oblasti Kompleksnykh Soedinenii" (Research in the Area of Complex Compounds). In 1908, he was appointed Professor of Inorganic Chemistry at S. Peterburgskii Universitet (St. Petersburg University). He occupied this chair, which was formerly held by Mendeleev, Konovalev, and Walden, until his death in 1922. He simultaneously occupied the chair of organic chemistry at the Leningradskii Khimiko-Tekhnologicheskii Institut (Leningrad Chemico-Technological Institute).

Chugaev's death can be attributed directly to the deplorable conditions in post-revolutionary Russia. When life in Petrograd had become almost impossible, he moved his wife and two sons to Vologda, a city some hundred miles north of Moscow. During one of his visits to his family, he contracted typhus, to which he succumbed on September 26, 1922. His death was a serious loss for chemistry in general and a real disaster for Russian chemistry in particular. His older son, Aleksander L'vovich, had died in 1921 after finishing secondary school. The younger, Vladimir L'vovich, a chemical engineer, died in 1941. Chugaev's wife, Aleksandra Aleksandrovna, died in Leningrad in 1942.

Some idea of the esteem in which Chugaev was held by his colleagues may be gained from the fact that following his death one of his students, E. Kh. Fritsman (1879–1942), devoted himself for many years to the posthumous publication of Chugaev's accumulated research. Even today Chugaev's influence still continues in the works of his students, of whom I. I. Chernyaev and A. A. Grinberg are prime examples.

Lev Aleksandrovich Chugaev was one of those individuals who devote themselves exclusively to science to the almost complete rejection of their personal lives. His *modus operandi* has been described by Lebedinskii (*2*). Chugaev seldom went to entertainments and he rested only infrequently. On those days on which he was free of lecturing duties, he would occupy himself with experimental work from early morning until late at night with only short hurried "breaks" for meals. Several times each day he found time to visit his students and co-workers in the laboratory, to discuss their work with them, and to communicate to them some of his own contagious enthusiasm. His students emulated his behavior by sometimes working until the early hours of the morning. Chugaev's quarters at St. Petersburg University occupied the same building as the laboratories and often in the middle of the night Chugaev would appear in the laboratory in his night robe to question his students about their work. He was impatient with the inevitable frustrations of experimental work, and his compulsive nature drove him to complete each project at a breakneck pace. The light in Chugaev's study would invariably burn until 4 or 5 A.M. where, surrounded by books and journals, he would be intent on his current research.

Chugaev's Work

Chugaev's earliest works were primarily biochemical and bacteriological. In studying the action of poisons on microorganisms, Chugaev sought a relationship between structure and toxicity. He linked toxicity with the presence of an aldehyde group and showed that a decrease in toxicity accompanies an increase in molecular weight and an even greater decrease occurs when the aldehyde is transformed into the corresponding ketone or acetal or when hydroxyl groups are introduced into the aldehyde molecule. On the other hand, introduction of a phenyl group or a halogen atom into the aldehyde or ketone molecule considerably increases its toxic properties.

In his study of phosphorescent bacteria, Chugaev attempted to relate the sugar concentration in the culture medium to the intensity of bacterial glow. He demonstrated that only very small concentrations (0.1%) of carbohydrates exert a favorable influence on the growth and glow of bacteria. Continuing this research further, Chugaev in 1898 proposed a new theory for the disinfecting action of the enzyme oxidase.

An interesting phenomenon early investigated by Chugaev was triboluminescence, the property possessed by some crystalline substances of becoming luminous when crushed, rubbed, or mechanically pressed together. Careful investigation of some 500 organic and inorganic substances showed about one fourth (chiefly organic) to be triboluminescent. The property appeared to be associated particularly with ring compounds. Certain groups such as hydroxyl, carbonyl, and secondary or tertiary amino especially favored triboluminescence; among many asymmetric compounds, the optically active antipodes were found to exhibit triboluminescence, whereas the racemic mixtures did not (*3*). Substitution of triboluminescent substances for zinc sulfide in the spinthariscope led to a paper on the theory of this instrument (*4*).

Terpenes

Chugaev's most outstanding contribution to terpene chemistry is undoubtedly his xanthogen method, which makes possible the conversion of alcohols into their corresponding optically-pure unsaturated hydrocarbons uncontaminated by isomeric compounds (*5*). The alcohol is first converted to the sodium alcoholate, which is then reacted with carbon disulfide to form a xanthogenate. Reaction of the latter with methyl iodide produces a xanthogen ester, which on careful heating decomposes to form the terpene hydrocarbon.

The xanthogen method enabled Chugaev to obtain for the first time optically and structurally homogeneous menthenes, inactive pinene, and other hydrocar-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

bons, to separate isomeric alcohols obtained in synthesis or in natural products, and to discover a number of new hydrocarbons—α- and β-thujene (tanacetene), thujane (tanacetane) (*6*), bornylene (*7*), isolimonene, and α- and β-cholesterylenes (*8*). At the time of its discovery, Chugaev's reaction served to introduce a measure of clarity into an extremely complex area of organic chemistry; it is still widely used today in organic synthesis.

Chugaev's contributions to organic chemistry were not limited to investigations of terpenes but ranged over the entire field. For example, his first published chemical paper (1895), a study of dihydroxymethylglutaric acid (*9*), carried out jointly with Nikolaĭ D. Zelinskiĭ of Hell-Volhard-Zelinskiĭ fame, was followed by a test for hydroxyl groups by use of organic magnesium compounds (*10*), an attempt to synthesize haemopyrrole (*11*), a new synthesis of α-diketones by the action of Grignard reagents on vinylideneoxanilide (*12*), selenomercaptans and their derivatives (*13*), an anomaly in the molecular refraction in substituted glyoximes (*14*), and an investigation of dithiocamphocarboxylic acid (*15*).

Anomalous Rotatory Dispersion

With the pure, optically active compounds placed at his disposal by his xanthogen method, Chugaev turned to a study of the optical properties of organic compounds, an area in which he soon became a world authority. As early as 1898, he had begun a study of the relationship between optical rotation and constitution. He found that in a homologous series the rotation increases to an approximately constant value with increasing molecular weight (Chugaev's rule) (*16*). He also observed the moderating effect of substituent groups on optical rotation.

Beginning in 1909, Chugaev initiated an intensive study of anomalous rotatory dispersion which resulted in more than a dozen publications within five years (*17*) and culminated in an invited paper presented before the Faraday Society in London on March 27, 1914. In this paper (*18*), which he was unable to present in person, he clearly discussed the three distinct causes which might independently give rise to anomalous rotatory dispersion.

The majority of colorless, optically active compounds exhibit normal rotatory dispersion, in which a plot of specific rotation, $[\alpha]$, versus the wavelength of incident light, λ, is hyperbolic and $[\alpha]$ increases regularly with decreasing wavelength (*19*). Anomalous rotatory dispersion exists in those cases in which the $[\alpha]$ versus λ curve has a maximum and passes through zero or in which $[\alpha]$ decreases with decreasing λ. Biot, who first discovered this behavior, showed that two substances, each of which has a normal rotatory dispersion separately, can, upon mixing, give a mixture with an anomalous rotation as a result of superposition, provided that the rotations of the two components at the same wavelength differ in both absolute value and sign. Such anomalous rotatory dispersion, due to nonhomogeneity, is called the Biot type.

Chugaev discovered a new type of anomalous rotatory dispersion—intramolecular anomalous dispersion. He was able to prepare compounds containing two oppositely rotating carbon atoms in which the Biot type anomaly was realized within the same homogeneous molecule (e.g., *l*-menthyl *d*,β-camphorsulfonate) (*17b*). He extended his studies to colored compounds and investigated the parallelism between optical rotation and absorption spectra (*17g*). He also showed that the Cotton effect, i.e., the fact that the maximum in the rotatory dispersion curve lies in the vicinity of the absorption in the visible portion of the spectrum, could be extended to substances whose absorption bands lie in the ultraviolet region (*17c,d*). In addition, Chugaev and his co-workers showed that substances possessing normal rotational dispersions at one temperature or in one solvent may become anomalous at another temperature, or in another solvent (*17h,m, 18*). A posthumous paper dealt with anomalous rotatory dispersion of essential oils (*20*).

Chugaev's studies of optical activity were not only of theoretical interest, but some were of analytical significance. For example, in 1911 he showed how measurement of the rotatory dispersion coefficient

$$\sigma = \frac{[\alpha]_F}{[\alpha]_C}$$

(where $[\alpha]_F$ and $[\alpha]_C$ are the specific rotations for Fraunhofer wavelengths *F* (4861 Å) and *C* (6563 Å), respectively) could be used for the analysis of optically active mixtures, viz., *d*- and *l*-menthone (*17c*). The same method could be applied to chemical reactions. Thus Chugaev was able to follow the decomposition of *l*-bornylxanthogenic acid into borneol and carbon disulfide by plotting rotatory dispersion curves at frequent intervals and noting the disappearance of abnormal dispersion and the gradual change to the curve characteristic of borneol (*17e*).

Chugaev's studies of optical properties were not confined to organic substances. Together with Sokolov (*21*), he made the first observation of the stereospecificity of inorganic coordination compounds, an important phenomenon whose systematic study is a relatively recent innovation. An octahedral complex containing three molecules of an optically active bidentate ligand would be expected to exist in a large number of stereoisomeric forms. For example, if all of the predicted isomers and all the total and partial racemates of the tris(propylenediamine)cobalt(III) ion were found, the chemistry of such complexes would be complicated (*19b*). However, Chugaev and Sokolov found that coordination compounds containing optically active ligands exist in only certain preferred forms; i.e., all the combinations are not of equal stability. In this case, the only isomers which were isolated were D-[Co *d*-pn$_3$]Cl$_3$ and L-[Co *l*-pn$_3$]Cl$_3$ and the totally inactive racemic mixture of these two.

Coordination Chemistry

Chugaev early noted the similarity between organic compounds and inorganic complex compounds; and although he was trained as an organic chemist, it is in coordination chemistry, a field in which he continued to work from 1904 until his death, that his fame securely rests. In his own words,

> The properties and transformations of complex compounds show that these compounds exhibit an amazing analogy to carbon compounds, which are dealt with in organic chemistry.

Here we have the same versatility of types, the same gradations in the degree of mobility of atoms, such as, for example, halide atoms in molecules, and the same phenomenon of isomerism, which are, as is known, extremely rare among inorganic compounds. From this viewpoint it appears extremely interesting and important to begin a systematic study of these compounds with those experimental and theoretical techniques which have already given us tremendous service in the area of organic chemistry (*2*).

The original objects of Chugaev's entry into this field were the compounds formed by Cu(II), Ni(II), and Ag(I) with organic imides, particularly succinimide (*22*). Chugaev demonstrated that a hydrogen atom of imides of carboxylic acids can be substituted by a metal ion to form abnormally colored salts, which in turn can form stable complexes with ammonia and aliphatic amines. Such compounds are related to the copper compounds obtained in the biuret reaction, a test for the presence of peptides, proteins, and amino acids which contain the —CONH— group. They differ only in their lesser stability toward water and in containing two molecules of succinimide corresponding to one of biuret. The red-violet potassium salt,

and the red compounds,

where a = an amine, are typical of this series. In order to ascertain how general were his observations of the behavior of amines toward copper succinimide, Chugaev extended his studies of reactivity to various amines and compounds of Cu(II), Ag(I), and Pt(II) and (IV) (*23*). He found that primary amines form complexes easily, secondary amines much less readily, and tertiary amines, except for pyridine, not at all.

Ring Stability

In order for a molecule with two potentially coordinating groups such as a diamine, $NH_2(CH_2)_nNH_2$, or an amino acid, $NH_2(CH_2)_nCOOH$, to function as a chelate group, it must be geometrically possible to form a ring of low strain. From organic chemistry, it is known that 5- and 6-membered rings are the most stable, whereas 4-membered rings are less stable and 3-membered rings are quite unstable (Baeyer's strain theory). That these relationships were completely applicable to complex compounds was shown by Chugaev as early as 1906 (Chugaev's rule of rings) (*24*). This rule served as a point of departure for stereochemical research not only by Chugaev but also by other workers. The widely used diagnostic method for determining the configuration of coordination compounds of Pt(II) by reaction with oxalic acid, which was subsequently developed by Chugaev's pupil A. A. Grinberg (*25*), provides an excellent example of the stability of a 5-membered ring:

Chugaev clearly showed the stability of pentatomic and hexatomic ring systems by comparing the ease of formation of complexes of Co(III), Ni(II), and Pt(II) with various diamines. Dimethylenediamine and trimethylenediamine readily formed complexes in contrast to higher polymethylenediamines. That 5-membered saturated ring systems are favored over 6-membered systems was shown by the lesser stability of trimethylenediamine compounds compared to the analogous propylenediamine compounds. Also, disulfides and diselenides, $R(S,Se)(CH_2)_n(S,Se)R'$, form complexes with Ni(II) and Cu(II) only when $n = 2$ (*26*). The tendency toward the formation of 5- and 6-membered rings and the greater stability of the former was further shown by Chugaev and Serbin's study of the formation of inner complexes of Cr(III) with various amino acids as a function of the separation of the carboxyl and amino groups (*27*). The α-acids formed inner complexes readily, whereas the β-acids did so with some difficulty; inner complexes could not be obtained at all with γ-, δ-, and ϵ-amino acids.

By assuming that ring compounds are more stable than open-chain compounds and that 5- and 6-membered rings are the most stable, Chugaev was able to explain the stabilities of numerous coordination compounds. Thus ammonia, monoamides, hydrazines, and γ-amino acids form relatively unstable compounds, whereas ethylenediamines and propylenediamines, amidines and amidoximes, 2,2′-bipyridines and phenanthrolines, α- and β-amino acids, nitrosoguanidines and aminoguanidines, and other compounds containing coordinating groups in the 1,2 or 1,3 positions form stable complexes. For the same reasons, compounds containing no nitrogen such as the salts of oxalic, α-oxy aliphatic, carbonic, and sulfuric acids are more stable than salts of open-chain monovalent acids.

Dioximines

Since Chugaev was trained as an organic chemist, it is not surprising that his first research on the metals of periodic group VIII (Fe, Co, Ni, Pd, and Pt) was a study of their reactions with organic reagents, viz., the α-dioximes (*28*). This resulted in his best known discovery, the reaction of Ni(II) with dimethylglyoxime, the first organic spot test reagent used to detect a metal ion. By use of this reagent one part of nickel may be detected in 2 million parts of water, even in the presence of large concentrations of cobalt. By use of a similar reaction, one part of iron may be detected in 165 million parts of water (*29*). The reaction was also applied to the separation and determination of pal-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

ladium by Wunder and Thüringer (*30*). The products formed by coordination of α-dioximes, which contain a labile hydrogen atom, with metallic ions and named dioximines by Chugaev are examples of inner complexes, i.e., nonelectrolytic compounds in which the coordinating groups through chelation satisfy simultaneously both the oxidation number and the coordination number of the metal ion. Because they may be extracted into organic solvents, such compounds are useful in effecting analytical separations. Their intense colors make them suitable for qualitative detections and quantitative colorimetric determinations of metal ions, and their insolubility forms the basis of a number of gravimetric methods. Along with Il'inskiĭ, who first employed α-nitroso-β-naphthol for the determination of cobalt in 1885 (*31*), Chugaev was a pioneer in the application of inner complexes to analytical chemistry.

Although the dioximines of cobalt, which were synthesized in great numbers by Chugaev (*32*), have no analytical significance, they were of great theoretical importance in the development of coordination chemistry. The Blomstrand-Jørgensen chain theory excluded the possibility of nonelectrolytic complexes, whereas the Werner coordination theory predicted the existence of such compounds (*33*). Since the number of such stable nonelectrolytic complexes was extremely small at the beginning of the twentieth century, the cobalt dioximines and the measurement of their conductances played a crucial role in the triumph of the coordination theory which Chugaev firmly supported.

The studies on dioximines were intimately connected with Chugaev's rule of rings, which runs through his research on complexes like a unifying thread. A single oxime group shows little tendency toward coordination, but when it can form part of a chelate ring, as in a dioxime, the nitrogen atom becomes a good electron pair donor. Symmetrical dioximes can exist in three isomeric forms:

Of the three isomers of dimethylglyoxime, Chugaev found that only the *anti* isomer forms the characteristic scarlet precipitate with Ni(*II*). He thus was able to use complex formation as a method for determining the isomeric configuration of α-dioximes. The scarlet precipitate was first believed by Chugaev to contain an improbable 7-membered ring (I), but this idea was later revised in favor of a 6-membered ring (II). Pfeiffer's (*34*) formulation of a 5-membered ring (III) has been supported by X-ray data (*35*) which showed the presence of multiple rings involving extremely strong hydrogen bonding (IV).

Platinum Compounds

Chugaev did not limit himself to the study of the coordination compounds of Fe, Co, Ni, Cu, and other non-noble metals, but soon began a comprehensive and systematic investigation of the complexes of platinum and its congeners. In fact, to quote Gilchrist, "the character of practically the entire Russian output of researches on the chemistry of the platinum metals reflects the influence of Chugaev" (*36*). Since for many years Russian chemists have made more contributions to this field than those of any other nation, this is no mean achievement. Chugaev explained his interest in this area as follows:

> Each element of the platinum group represents, as it were, its own miniature organic chemistry, in which, as if in a mirror, are reflected the features of its chemical individuality. The combined totality of these organic chemistries, however, deviates from general similarities to the compounds of carbon so much that the classic structural theory of Kekulé-Butlerov proved inapplicable; a different, broader, and more flexible theory became necessary, the attempt at the discovery of which was made by the professor from Zürich, Alfred Werner (*2*).

Chugaev, like chemists before him and after him, realized that stereochemical studies could best be made with elements whose complexes were stable, i.e., with the platinum metals.

Chugaev's earliest and most extensive research in this field dealt with coordination compounds of organic sulfides and disulfides (*37*). A bibliography of such work has been compiled by E. Kh. Fritsman (*38*). Werner's coordination theory predicts only two stereoisomers (*cis* and *trans*) for compounds of type $[MA_2B_2]$ if the configuration is square planar. In an important study in this series (*39*), Chugaev showed by its reaction with tetrammineplatinum(II) chloride to give Magnus' green salt that the third (γ) isomer of $[Pt\{(CH_3)_2S\}_2Cl_2]$ was actually an electrolytic "polymerization" isomer, rather than a stereoisomer:

$$[Pt\{(CH_3)_2S\}_4][PtCl_4] + [Pt(NH_3)_4]Cl_2 \rightarrow [Pt(NH_3)_4][PtCl_4]\downarrow + [Pt\{(CH_3)_2S\}_4]Cl_2$$

In the same work, it was also shown that the same relationships hold for the more stable disulfide complexes. Thus the red form of empirical formula $[Pt\{C_2H_4(SEt)_2\}Cl_2]$ was shown to be $[Pt\{C_2H_4(SEt)_2\}_2][PtCl_4]$. Since this time, similar examples of "polymerization" isomerism have been reported (*40*). Under certain conditions, such as heating, the "polymerization" isomer may decompose to form the monomer (*39, 41, 42*). This phenomenon of "depolymerization" is not limited to Pt(II) complexes, but also

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

occurs in the case of complexes containing both Pt(II) and (IV),

$$[Pt\{(CH_3)_2S\}_4][PtCl_6] \xrightarrow{\Delta} [Pt\{(CH_3)_2S\}_2Cl_2] + [Pt\{(CH_3)_2S\}_2Cl_4] \quad (43)$$

as well as complexes containing more than one metal,

$$[Ag(NH_3)]_2[PtCl_4] \xrightarrow{\Delta} [Pt(NH_3)_2Cl_2] + 2AgCl \quad (42)$$

In accordance with Chugaev's rule of rings, organic disulfides were found to form more stable complexes than do the monosulfides; of the compounds, $RS(CH_2)_nSR$, only compounds with $n = 2$ were found to form stable, well-characterized chelates (*26*, *39*, *41*, *44*, *45*). By conductance measurements (*44*), Chugaev was able to follow the course of reactions such as

$$[Pt\{RS(CH_2)_nSR\}Cl_2]^0 + RS(CH_2)_nSR \rightarrow [Pt\{RS(CH_2)_nSR\}_2]^{2+} + 2Cl^-$$

and thus determine the relative stabilities of different ring systems. Use of the same physicochemical method (*46*) to determine the extents of dissociation and reaction of the isomers of organic monosulfides such as $[Pt(Et_2S)_2Cl_2]$ (*47*), led Chugaev to conclusions which were later explained by his student Chernyaev in terms of the *trans* effect (*48*).

Another series of platinum complexes to which Chugaev devoted much time was the chloropentammines of tetravalent platinum. Every book dealing with coordination chemistry, whether introductory or advanced, includes almost without exception the familiar V-shaped plot of the molar conductances of the series of Pt(IV) ammines versus the number of chlorine atoms introduced into the coordination sphere. The popularity of this graph no doubt stems from the numerous principles it illustrates—the formation of a series of complexes due to stepwise displacement of a ligand by an anion entering the coordination sphere, the effect of such entry on the charge of the complex and on the number of ions present, the determination of the number of ions by conductance measurements, and the preservation of the coordination number during these changes. A graphical presentation usually omits the fact that the crucial second series in this group of Pt(IV) ammines, the chloropentammines which were predicted by Werner's theory, was missing until Chugaev was finally able to synthesize a compound by the action of ammonia on ammonium hexachloroplatinate(IV) (*49*):

$$(NH_4)_2[PtCl_6] + NH_3 \rightarrow [Pt(NH_3)_5Cl]Cl_3 + 2NH_4Cl$$

As predicted, Chugaev and Vladimirov found the conductance, Λ_{1024}, (404 ohm^{-1} cm^2, 4 ions) intermediate between that for $[Pt(NH_3)_6]Cl_4$ (523 ohm^{-1} cm^2, 5 ions) and $[Pt(NH_3)_4Cl_2]Cl_2$ (229 ohm^{-1} cm^2, 3 ions). They also established the charge on the cation in solution by measurement of the critical coagulation concentration (CCC), a technique based on the Schulze-Hardy rule which states that the CCC at which an electrolyte causes rapid coagulation of a colloidal system depends on the charge of the counter-ion (*50*). In view of its importance in the development of coordination chemistry, in 1925 $[Pt(NH_3)_5Cl]Cl_3$ was officially named "Chugaev's salt" by decree of the Fourth Mendeleev Congress.

The newly discovered Pt(IV) acidopentammines also enabled Chugaev to make a valuable contribution to acid-base theory. The classical studies in this area by Niels Bjerrum and J. N. Brønsted had shown that hydrates, especially those of highly charged metallic ions, are acidic since the coordinated water molecules can lose protons to form hydroxoaquo complexes:

$$[Al(H_2O)_6]^{3+} + OH^- \rightarrow [Al(H_2O)_5(OH)]^{2+} + H_2O$$

Chugaev showed that an analogous reaction takes place with ammines, but to a lesser extent than with hydrates, and he simultaneously discovered a new series of acidoamidotetrammines of Pt(IV) (*49a,b*, *51*):

$$[Pt(NH_3)_5Cl]^{3+} + OH^- \rightarrow [Pt(NH_3)_4(NH_2)Cl]^{2+} + H_2O$$

The compounds of this new series are basic and readily react with acid to reform the original acidopentammines:

$$[Pt(NH_3)_4(NH_2)Cl]^{2+} + H^+ \rightarrow [Pt(NH_3)_5Cl]^{3+}$$

Chugaev also prepared a new series of Pt(IV) hydroxopentammines and showed that $[Pt(NH_3)_5OH]^{3+}$ is a much weaker base than the corresponding cobalt(III) complex, $[Co(NH_3)_5OH]^{2+}$, which has a smaller charge (*49a,b*, *51a,c*, *52*). The acidity of other coordinated molecules which contain protons has since been demonstrated by other workers, particularly Chugaev's student Grinberg.

Chugaev made a thorough study of the nitro complexes of divalent platinum and of the relationships between the reactions of the members of the series $[Pt(NH_3)_4](NO_2)_2$, $[Pt(NH_3)_3NO_2]NO_2$, *cis*- and *trans*-$[Pt(NH_3)_2(NO_2)_2]$, and $K_2[Pt(NO_2)_4]$ (*53*). On heating the second member of this series, Chugaev obtained the *trans* isomer of the third member:

This reaction, which shows that the molecule of ammonia *trans* to a highly electronegative NO_2 group is more easily replaced than are the two mutually *trans* ammonia molecules, was later explained by Chernyaev's *trans* effect (*48*).

Chugaev and co-workers first prepared and established the structures of coordination compounds of platinum containing ligands such as aminoacetal (*54*), nitriles (*55*), isonitriles (*56*), hydroxylamine (*52*, *57*), water (*58*), the sulfito group (*59*), and hydrazine (*60*). Although the hydrazine molecule contains two nitrogen atoms, it occupies only a single coordination position because 3-membered rings are unstable (Chugaev's rules). Since one of its nitrogen atoms can still act as an electron pair donor, such a hydrazine complex behaves as a base and reacts with acids:

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Chugaev was also interested in the conversion of Pt(II) complexes to Pt(IV) complexes; he employed hydrogen peroxide (*61*), oxone (*61*), oxygen (*62*), and peroxydisulfate ion (*62*) as oxidizing agents.

In addition to preparing new platinum complexes, Chugaev devised improved methods for the synthesis of known compounds. A case in point is "Cleve's triammine," $[Pt(NH_3)_3Cl]Cl$, for many years the least available of Pt(II) complexes because of its indefinite method of preparation. Chugaev (*63*) was able to synthesize this valuable intermediate from one of the best known Pt(II) complexes, Peyrone's salt, *cis*-$[Pt(NH_3)_2Cl_2]$ (*64*). He also devised a valuable test involving the use of sulfuric acid to distinguish *cis*-$[Pt(NH_3)_2Cl_2]$ from its *trans* isomer (*65*). A novel method utilizing platinum black for the quantitative reduction of K_2PtCl_6 to K_2PtCl_4, a versatile starting material for the synthesis of Pt(II) complexes, (*66*) constituted a great improvement over existing procedures (*67*).

Other Platinum Metals

By use of thiourea, a reagent introduced into platinum chemistry by Kurnakov (*68*), Chugaev was able to prepare a new brilliant red osmium(III) compound, $[Os(NH_2CSNH_2)_6]Cl_3 \cdot H_2O$, analogous to the luteo salts of trivalent Co, Cr, Rh, and Ir. Formation of this compound provided a sensitive analytical test for osmium by means of which one part of osmium can be detected in 100,000 parts of water (*69*). Evidence for the acidic nature of osmium(VIII) oxide was shown by Chugaev's preparation of series of well-defined crystalline compounds, $M_2[OsO_4(OH)_2]$, and unstable compounds, $M_2[OsO_4F_2]$, by reaction of OsO_4 with alkali metal hydroxides or alkali metal fluorides, respectively (*70*). A comprehensive review of Chugaev's work on osmium derivatives from 1916 to 1925 has been given by E. Kh. Fritsman (*71*).

Chugaev's investigations of complexes of palladium with organic monosulfides and disulfides showed these compounds to be intermediate in properties between the corresponding complexes of nickel and platinum (*72*). His studies of hydrazine complexes of iridium led to the discovery of $H[Ir(N_2H_5)Cl_5]$ and its salts (*73a,b*). Ever alert to analytical applications of chemical reactions, Chugaev devised a novel method for detecting iridium in the presence of other platinum metals (sensitivity, 1 part of Ir in 6 million parts of water) based on the oxidation to malachite green of the leuco base of malachite green by $IrCl_6^{2-}$ in acid solution (*73c*).

The scarcity of nonelectrolytic complexes and their crucial importance in the development of coordination chemistry has been mentioned. A series of complex nonelectrolytes of the type $[Rh(NH_3)_3X_3]$, analogous to the corresponding compounds of Co, Cr, and Ir were discovered by Chugaev (*74*). By use of rhodium black at 100°C, Chugaev was able to convert catalytically a mixture of formaldehyde and sodium hydroxide to sodium formate (*75*).

Miscellaneous Works

Some of Chugaev's works which defy classification in the above categories may give an idea of his versatility and wide interests. Among such works are his apparatus for the determination of solubilities at different temperatures (*76*), compounds of univalent nickel (*77*), compounds of aluminum bromide with hydrocarbons (*78*), and studies on the reducing power of sulfurous (*79*) and hyposulfurous acids (*80*). In addition to his two books on coordination chemistry, "O Khimicheskom Stroenii Kompleksnykh Soedinenii" (On the Chemical Structure of Complex Compounds) (1910), and "Strukturno- i Stereokhimicheskie Predstavleniya v Oblasti Neorganicheskoi Khimii. Novye Idei v Khimii" (Structural and Stereochemical Concepts in the Field of Inorganic Chemistry. New Ideas in Chemistry) (1914), Chugaev was the author of two works on the history of chemistry, "Discovery of Oxygen and Theory of Burning" and "Dmitriĭ Ivanovich Mendeleev. Life and Activities."

Chugaev was an outstanding speaker and popularizer of scientific knowledge, and his lectures always attracted large audiences. His skillfully written scientific books and articles contributed in a considerable degree to the dissemination and development of chemical knowledge in the USSR.

Applied Works

Chugaev was no "ivory tower" scientist. During World War I, this versatile chemist, who was later awarded the coveted Lenin Prize by the Soviet government, was one of the initiators of the Voennii-Khimicheskiĭ Komitet (Military Chemical Committee) at the Russkoe Fiziko-Khimicheskoe Obshchestvo (Russian Physical-Chemical Society). At this time he conducted research on medicines and explosives, both sorely needed by a government poorly prepared for the conflict. He also participated actively in the organization and work of the Gosudarstvennyĭ Institut Prikladnoĭ Khimii, GIPKh (State Institute of Applied Chemistry), founded by N. S. Kurnakov (*68*). At the Opytnaia Zavod (Experimental Plant), the first research in Russia on the preparation of red phosphorus, phosphoric anhydride, chromyl chloride, and metallic arsenic was carried out under his direction. In response to an increased demand for platinum catalyst to be used in the contact process for manufacturing sulfuric acid, Chugaev, together with Khlopin and Lebedinskiĭ, devised industrial methods for the refining of platinum and its congeners. He also participated actively in research at the Pishcheviĭ Institut (Nutrition Institute).

The Platinum Institute. In 1915, N. S. Kurnakov, V. I. Vernadskiĭ, and A. E. Fersman organized as part of the Akademiia Nauk (Academy of Sciences), a commission known as Komissiia po Izucheniiu Estestvenno Proizvodstvennykh Sil Rossii, KEPS (Commission for the Study of Russian Natural Productive Sources). In response to this commission's appeal, Chugaev drafted a report in which he argued that platinum, one of Russia's most valuable natural resources, should not be exported in a raw form, but that a state monopoly be created for locating, producing, and processing this important metal. He proposed the formation of an institute with the following functions: comprehensive research on the metals of the platinum group; search for new and useful alloys of these metals;

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

systematic study of the coordination compounds of these metals, including a search for new types of such compounds, their syntheses, reactions, and methods for determining their configurations; development and perfection of methods for the refining and analysis of the platinum metals, as well as for the exploitation of low-grade ores.

It was only after the October (1917) Revolution that Chugaev's dream became a reality. In 1918, he was appointed the first director of the newly created Institut po Izucheniiu Platiny i Drugikh Blagorodnykh Metallov (Institute for Study of Platinum and Other Noble Metals) of the Akademiia Nauk S.S.S.R. (Academy of Sciences of the USSR). Members of the staff included N. S. Kurnakov, V. I. Vernadskiĭ, F. Iu. Levinson-Lessing, I. I. Chernyaev, V. G. Khlopin, E. Kh. Fritsman, V. V. Lebedinskiĭ, N. I. Podkopaev, N. I. Stepanov, and N. K. Pshenitsyn as executive administrator. On Chugaev's death in 1922, Kurnakov became director of the Institute.

In accordance with the Soviet policy of creating a Russian chemical literature, the *Izvestiia Instituta po Izucheniiu Platiny i Drugikh Blagorodnykh Metallov* was founded in 1920 by Chugaev in order to publish the Institute's research results. From 1921 to 1935, virtually the entire Russian literature on platinum metals appeared in the 12 volumes of this journal, whose editors were Kurnakov, Fritsman, and Zvyagintsev. In 1934, the Platinum Institute, the Institute of Physicochemical Analysis, and the General Chemistry Laboratory of the Academy of Sciences of the USSR merged into the Institut Obshchei i Neorganicheskoĭ Khimii, IONKh (Institute of General and Inorganic Chemistry), with headquarters in Moscow and with Kurnakov as its director. Beginning with 1936 the journal was renamed *Izvestiia Sektora Platiny i Drugikh Blagorodnykh Metallov;* it ceased publication in 1955, being displaced by the new *Zhurnal Neorganicheskoi Khimii* (Journal of Inorganic Chemistry).

Unfortunately, Chugaev did not live to see the close cooperation which later developed between the Platinum Institute and Russia's platinum industry. Within a comparatively short time after his death in 1922, his ideas concerning the mutual dependence of theory and practice began to materialize, as the Institute rendered substantial aid to the young but growing industry. Even today Chugaev's former students continue to fulfill his prediction that "each and every scientifically founded conclusion or approximation, each pattern which conforms to a rule, each carefully established fact which is concerned with the chemistry of the platinum metals will sooner or later have its practical equivalent."

During his short career, Chugaev created around himself a ranking school of organic chemists among whom may be mentioned F. V. Tserevitinov, G. V. Pigoulevskii, V. A. Fomin, N. A. Schloesinger, and A. A. Glebko. However, it is the "Chugaev School" of inorganic chemists, which includes names such as I. I. Chernyaev, V. G. Khlopin, A. A. Grinberg, V. V. Lebedinskiĭ, and V. K. Pshenitsyn, that has achieved the greater fame. Under Chernyaev's direction, the Institut Obshcheĭ i Neorganicheskoĭ Khimii imeni N. S. Kurnakova Akademii Nauk, S.S.S.R. (N. S. Kurnakov Institute of General and Inorganic Chemistry of the USSR Academy of Sciences), IONKh, today continues the work initiated by Chugaev. The outstanding achievements of this, one of the world's principal centers for the systematic study of coordination compounds, form an enduring testimonial to the genius, foresight, and inspiring influence of Lev Aleksandrovich Chugaev.

Acknowledgments

The author wishes to acknowledge the assistance of *Akademik* Ilya I. Chernyaev, Direktor, Institut Obshcheĭ i Neorganicheskoĭ Khimii imeni N. S. Kurnakova Akademii Nauk S.S.S.R., Moscow. He also wishes to thank Alexander Beck, Dept. of Slavic Languages and Literatures, University of California, Berkeley, for assistance in translating the Russian biographical article (*2*). The present study resulted from interest in Chugaev aroused by a research project on the separation of inorganic geometric isomers sponsored by the Research Corporation, the National Science Foundation (NSF-G-11241), and the Petroleum Research Fund, administered by the American Chemical Society (Grant PRF 1152-B).

Division of CHEMICAL EDUCATION

American Chemical Society

. . . *from the* TREASURER

WILLIAM G. KESSEL

Supporting the vigorous program of the Division of Chemical Education is a sound financial structure. Member responsibility to this structure starts with faithful payment of annual dues of $1.50 or for Division Affiliates, $2.00, payable to the Treasurer, January 1 of each year. It goes beyond this to include an approving knowledge of the fiscal policy of the Division. This Treasurer's Report provides each member an opportunity to review this policy and, when confronted with a question, an occasion to write the Treasurer for clarification.

DIVISION ACCOUNT

Receipts:		
Balance, December 31, 1963		$1,781,06
Dues	$3,507.55	
Dividends and interest	3,246.10	
(from Journal Account; completes years 1961, 1962, 1963)		6,753.65
Total receipts		$8,534,71
Expenditures:		
Postage	$ 534.00	
Office supplies	388.80	
Office services	436.55	
Printing	926.39	
Committees	915.62	
Bank charges	5.52	
Journal subscriptions	90.00	
Total expenses		$3,296.88
		$5,237.83
Checks outstanding		342.80
Balance, September 1, 1963 (First National Bank, Terre Haute, Indiana)		$5,580.63

JOURNAL ACCOUNT

Receipts:		
Balance, December 31, 2962		$22,390.87
Chemical Educating Publishing Company, share for 1962	$12,408.84	
Total receipts		$34,799.71
Expenditures:		
Dividends transferred to Division Account	$ 1,844.73	
	1,401.37	
Extra pages—1962 Journal	4,786.52	
Purchase of 17 shares ACS Cash and Investment Pool	20,000.00	
Total expenses		$28,032.62
Balance, September 1, 1963		$ 6,767.09
Assets:		
Bank balance, September 1, 1963		$ 6,767.09

Report of the New England Association of Chemistry Teachers

Official Business

Meetings

Five one-day meetings and a special Twenty-Fifth Anniversary Summer Conference were held during the year 1962–63, under the guidance of President Leallyn B. Clapp of Brown University.

317th Meeting: October 15, 1962, at Laconia Memorial Junior High School, Laconia, N. H. Arranged by Alan H. Davis of Plymouth (N. H.) State College, Chairman of the Northern Division.

318th Meeting: December 1, 1962, at Boston College, Chestnut Hill, Mass. Arranged by David W. Parfitt of Brookline, (Mass.) High School, Chairman of the Central Division.

319th Meeting: February 9, 1963, at Rhode Island College, Providence. Arranged by Robert M. Sherman of Roger Williams Junior College, Providence, Chairman of the Southern Division.

320th Meeting: April 6, 1963, at Central Connecticut State College, New Britain. Arranged by John Prymak of William Hall High School, Hartford, Chairman of the Western Division.

321st Meeting: May 11, 1963, at Clark University, Worcester, Mass. Arranged by David W. Parfitt.

The *Twenty-Fifth Annual Summer Conference* was held August 19–24, at the University of New Hampshire with Alexander R. Amell of the University as the *Host*. Co-Chairmen in charge were: *Program:* Raymond D. Cool, Madison College, Harrisonburg, Va.; *Arrangements:* Maurice Bernier, Exeter (N. H.) High School. The Registrar-Treasurer was Martha Dunbar, Centenary College, Hackettstown, N. J., and the Conference Secretary was Dorothy W. Gifford, Lincoln School, Providence.

In addition to the usual varied and stimulating program, a special trio of speakers were invited for *Twenty-Fifth Anniversary Day:* Dr. William F. Kieffer of the College of Wooster, Wooster, Ohio, Editor of the JOURNAL OF CHEMICAL EDUCATION, who spoke on "The Mole Concept"; Dr. Calvin A. Van der Werf, President of Hope College, Holland, Michigan, who spoke on "Acids and Bases"; and Dr. Edward L. Haenisch, Wabash College, Crawfordsville, Indiana, winner of this year's SAMA Award, who spoke on "Teaching Descriptive Chemistry." Activities of the day were climaxed by "An Evening of Nostalgia" in which photographs of former conferences collected from many sources were presented by Carl Swinnerton of Pomfret, Conn. A silver punch bowl to be used at the evening socials was presented in honor of the six members who have attended all twenty-four previous conferences. Five of these were registered at this conference, completing their first quarter century of faithful attendance:

Mr. and Mrs. Grover C. Greenwood (retired), Bridgeport, Conn.

Mr. Alfred R. Lincoln, Hamden College of Pharmacy, Williamansett, Mass.

Miss Evelyn L. Murdock, Stonington High School, Stonington, Conn.

Miss Elsie S. Scott, Northfield School for Girls, Northfield, Mass.

Appointments and Elections

The officers elected by the membership for the fiscal year 1963–64 have been published in the *Report:* THIS JOURNAL, 40, 440 (1963). As noted there, Harold A. Iddles, Professor of Chemistry at the University of New Hampshire and presently Program Director for the Elementary and College Teachers Program, NSF, was elected to Honorary Membership. He was presented with a certificate at the University where he had served so well as Chairman of the Chemistry Department.

Appointments for the year include:

Editor of the Report: Robert D. Eddy, Tufts University, Medford, Mass.

Editor of the News-Letter: Howard I. Wagner, State Director of Science Education, Concord, N. H.

Assistant Editor of the News-Letter: Angela M. Trovato, Branford High School, Branford, Conn.

Publicity Agent: Everett F. Learnard, Norwood High School, Norwood, Mass.

New President of NEACT

Guy F. Burrill

Guy Francis Burrill, Chairman of the Science Department and chemistry teacher at Keene (N. H.) High School, took office on July 1, 1963 to become the Association's thirty-sixth President. He earned the BS Degree from the University of New Hampshire in 1937. He was further awarded the MEd degree by the University in 1954. His teaching began at Newport, N. H. in 1931. In 1943–44 he was a Field Director for the American Red Cross, but returned to the classroom in 1944. Since 1960, he has also been the chemistry teacher in the Nurses Training School of the Elliot Hospital in his own community.

Twice he has been Chairman of the Science Division of the New Hampshire Teachers Association. He was on the New Hampshire State Science Fair Committee from 1953–58. He also has been active in NSTA affairs and currently is president of the Keene Education Association. In NEACT, he has assisted in many different capacities, having worked particularly to assure the success of the Summer Conferences.

Guy's summers have not been idle. He was a Research Chemist with the F. A. Putnam Company in 1945, and a General Electric Fellow in 1952. He attended Harvard on a DuPont Scholarship in 1954 and in 1955 was at the Oak Ridge Institute of Nuclear Studies. In 1959 and 1960 he was an Instructor in Chemistry at the Simmons College NSF Institute for Teachers. In 1961 and 1962 he taught chemistry in the Liberal Studies Program at the Mount Herman School for Boys.

Activities

The Association continues to grow with an active membership on September 1 of 1030. In addition, there are 14 honorary members, 33 honorary and active members, and 2 complimentary members. In the sixty-five years since the Association's founding, some 2850 persons have joined our ranks.

During the past year, the largest attendance at a one-day meeting was 125, at Boston College on December 1. A registration of more than 272 members and guests at the Summer Conference made this meeting one of the largest the Association has ever held.

Looking Ahead

The *Twenty-Sixth Summer Conference* will be held in August, 1964, at Colby College, Waterville, Maine. The program will be under the direction of Dorothy W. Gifford of the Lincoln School, Providence, R. I. Alan H. Davis of Plymouth (N. H.) State College will be in charge of arrangements.

LETTERS

To the Editor:

For the past year I have been making 35-mm slides for lecture use at a cost of about 10 cents a slide in a way which I believe to be simpler than the methods suggested in the article that appeared in the September, 1963 issue, (**40**, 483 (1963)). I use a 35-mm single lens camera with close-up lenses.

The combination of a +2 and a +4 lens permits copying in the range of about 2 × 3 to 9 × 14 in. The lenses and adapters may be purchased for about $10. I do the copying on my desk using a fluorescent desk lamp as the light source. I use 36-exposure (Sears Tower) indoor *color* film with prepaid processing. The advantages of using color film for slide making are: (1) colored subjects can be rendered in color; (2) the slides are positives; and (3) the slides are mounted by the processor at no extra cost. The only disadvantage that this procedure entails is the 1–2 week wait for processing.

RUBIN BATTINO

ILLINOIS INSTITUTE OF TECHNOLOGY
CHICAGO

To the Editor:

The article by F. F. Mikus on "Simple Preparation of Phosphors" (THIS JOURNAL, **40**, 362 (1963)) is much appreciated. His description of $KCl\text{-}SbCl_3$ phosphor prepared at room temperature is an example of a reaction which should be of interest to those who wish to demonstrate or examine solid state reactions. Another such reaction, also carried out under filtered ultraviolet light, is the bright yellow to yellow-green fluorescent system which results when a dry mixture of zinc stearate and 8-hydroxyquinoline (a few tenths to a few per cent of the latter) is gently warmed on a water bath in the presence of ammonia (a small wad of filter paper soaked in NH_4OH and dropped into the mixture suffices). As the ammonia fumes pass through the mixture, the otherwise dull blue fluorescence dramatically changes to the brighter and more vivid emission. The mixture is extremely sensitive to small concentrations and should have possibilities for detecting traces of the gas. The reaction can also be used as a simple and quick method for distinguishing zinc soaps from other metallic soaps.

BOOK REVIEWS

Organic Chemistry

Donald J. Cram, University of California at Los Angeles, and *George S. Hammond*, California Institute of Technology, Pasadena. 2nd ed. McGraw-Hill Book Co., Inc., New York, 1963. Figs. and tables. 17.5 × 28 cm. $10.75.

"If we can get a handle attached to this carbon, a bimolecular substitution ought to give us the alcohol we want without much rearrangement." Anyone who has spent any time in organic research lab has heard comments very similar to that. More and more often, practicing chemists think in terms of substitution, elimination, and addition reactions, etc., and, in fact, many recent very elegant syntheses simply could not have been planned without a detailed understanding of reaction mechanisms.

"We will now discuss the alcohols, considering first methods by which they may be prepared, and then we shall discuss the various reactions which they may be induced to undergo." Anyone who has spent any time in an organic classroom has all too often heard the instructor carry on as if nothing had happened in the past 40 years. Fortunately, in their new edition of "Organic Chemistry," Cram and Hammond continue their practice of encouraging first-rate organic chemists to talk to their students as they talk to each other.

While this text has been extensively revised and rewritten, all of the essential features of the original have been retained (reviewed in J. Chem. Educ., **37**, 325–6, [1960]). The most important of these features is the classification of organic reactions according to mechanism, rather than according to functional group.

As before, the text begins with several chapters on vocabulary, i.e., nomenclature of organic compounds, and some of their more typical reactions. This section now encompasses seven chapters instead of the four previously used, but this has been accomplished not so much by the addition of new material, but rather by a less compressed discussion with more illustrative examples and, primarily, by converting four long chapters into seven shorter, more easily digestible ones. The reactions described have been very carefully selected for their simplicity and use in synthesis and structure proof. Generally this section is excellent but there does seem to be a little confusion as to what happens in a Kuhn-Roth determination (see pp. 42 and 46).

The next four chapters on structure and physical properties have been very considerably revised, expanded, and vastly improved. For example the chapter on the Character of Chemical Bonding has been expanded from 25 to 33 pages and almost completely reorganized. The molecular orbital formulation is presented first, followed by the valence bond method. The chapter is quite remarkable for its clarity and readability, whereas it must be admitted that the student using the first edition needed considerable assistance. The remaining chapters on Stereochemistry, Physical Properties, and Correlation of Structure and Reactivity are less drastically revised.

Chapter 12, which has been almost completely rewritten and much improved, prepares the way for a consideration of the various chemical reactions class by class. The reactions themselves, classified according to mechanism, are discussed in Chapters 13 through 23. Here the most important changes involve the order of presenting the reactions, although new reactions such as hydroboration have been included where appropriate. The chapter on elimination reactions has wisely been moved closer to the front, and a discussion of electrophilic substitution at saturated carbon deferred to Chapter 20. Unfortunately electrophilic substitution at unsaturated carbon still comes pretty late in the game (Chapter 19). The section on radical reactions (chapter 22) is probably the most revised and enlarged (from 12 to 24 pages) one in this section, reflecting the tremendous increase in interest in photochemical reactions.

Following the discussion of the various reactions, a completely new chapter entitled Organic Synthesis appears. This chapter does not present any new material, but does show how an expert artist can design and build the sort of molecule he needs. It is hoped that at least some students will read this chapter for quite a few will appreciate and enjoy it. All teachers will find these pages sheer pleasure.

The remaining nine chapters on special topics are not too much changed from the first edition with the exception of Chapter 31, on spectra. In this chapter the section on dyes has been eliminated and the pages devoted to ultraviolet, infrared, and NMR much expanded. A completely new section on emission spectra has been added.

The problems at the end of each chapter are excellent and more numerous than in the first edition. Also provided are several Reading References but these are usually to standard texts (Ingold, Hine, Gould, Wheland, Fieser and Fieser, Organic Reactions, etc.) and it is regrettable that only in one or two instances is the original literature cited. The admirable practice of citing yields in most reactions is continued.

The type used in this new edition will be particularly clear. The technique of using color in equations to focus the readers attention upon the centers of reactivity is a good idea but it will take some getting used to.

The text should certainly be more "teachable" than the first edition which this writer has used successfully not only with classes of chemistry majors at the junior level but also, with careful choice of chapters, with arts students at the sophomore level. However, one must trust the authors. The natural tendency is to try to expand the "vocabulary" section into a full course and if so one might as well throw away the book. But if taken as directed this text is powerful medicine as well as being lots of fun for both teacher and student.

Principles of Chemistry

Donald C. Gregg, University of Vermont, Burlington. 2nd ed. Allyn and Bacon Inc., Boston, 1963. xv + 716 + 62 pp. Figs. and tables. 17 × 23.5 cm. $8.50.

The second edition of this textbook is printed in large, easy-to-read type that necessitates more pages for essentially the same number of words. Each chapter, each paragraph, and each sentence appears to have been carefully considered in the revision.

Several changes have been made in the order of topics. The two chapters devoted to the gaseous state in the first edition have been combined into a single chapter which now comes much later in the book. Consideration of atomic structure now begins in the fourth chapter rather than the ninth. Organic chemistry is still the topic of the final chapter, but nuclear chemistry has been moved to the chapter next to the last.

In the treatment of the gaseous state, the measurement of pressure is an example of the kind of topic that has been condensed to make room for topics not formerly considered. The new topics include the equation of state for the ideal gas, the van der Waals equation, the Boltzmann principle, entropy, and the plasma state.

New topics have also been introduced into the discussion of atomic structure and chemical bonding. These include the spatial orientation of atomic orbitals, the hybridization of orbitals, pi and sigma bonds, and stereoisomerism in complex ions. The discussions of geometric isomerism and of optical isomerism in organic chemistry are retained from the first edition.

The equilibrium constant expression is no longer derived by equating rate expressions for the forward and reverse reactions. The treatment of chemical equilibrium is now more thermodynamic, with the discussion involving enthalpy, entropy, and Gibbs free energy.

The only chapters devoted specifically to descriptive chemistry in the first edition were a chapter on oxygen and another on hydrogen. In the new edition there are six chapters of descriptive chemistry entitled Hydrogen, The Oxygen Family, The Halogens, The Nitrogen Family, The Representative Metals, and the Transition Metals.

Gregg retains his practice of using such operational symbols for the elements as $\overline{|Cl}$ so that the electronic formula for hydrogen chloride is written $H\text{-}\overline{Cl|}$ instead of $H:\ddot{Cl}:$ or $H\text{-}\ddot{Cl}:$. He represents the hydrated proton as OH_3^+ and calls it the oxonium ion. He discusses the "unlocalization of electrons" but has discarded the word "resonance." In his treatment of *p*H he has discontinued all mention of *p*OH.

The author has again written a scholarly text and has frequently employed an apt manner of expression, as when he writes: "The atomic weights of the elements are numbers on a scale." It is difficult to understand why he retains the gram-atom, which he uses "to represent the amount of matter in one mole of atoms."

The book is well printed, well bound, well indexed, and well written. The list of suggested readings has been shortened and no longer includes specific journal articles classified according to subject. The 25 photographs of the first edition are missing, but the text is fully illustrated with diagrams. Each chapter is again accompanied by good questions and problems, with answers to problems in the back of the book.

The first edition of this text was published in 1958 and was reviewed in THIS JOURNAL (**37**, 107 [1960]). Meanwhile, the author has written another text entitled "College Chemistry" which was published in 1961 and reviewed in THIS JOURNAL (**39**, A834 [1962]). Although the second edition of "Principles of Chemistry" is organized much like "College Chemistry," the level at which the new book is written is the highest of the three.

Athens

Fundamentals of General Chemistry

C. H. Sorum, University of Wisconsin, Madison. 2nd ed. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1963. 707 pp. Figs. and tables. 17.5 × 24 cm. $8.50.

Readers who are acquainted with the first edition of this freshman textbook (reviewed by Jacob Kleinberg, THIS JOURNAL, **33**, 304 [1956]) will find that the second edition exhibits the careful, logical introduction and development of concepts and the same clear, concise, and readable style which characterized the first. In the new edition, increased emphasis has been given to atomic structure, chemical bonding and molecular geometry, and to redox phenomena. Numerous changes in the order of presentation of topics have also been made.

The first ten chapters are devoted to laying the foundations for, and presenting, the current ideas of atomic structure and chemical bonding. New chapters on Ionization Potential and Chemical Bonding appear in this part. A brief discussion of hybrid orbitals is included. Following chapters on hydrogen and water, comes a section concerned primarily with equilibrium, solutions, and acid-base theory. Redox potentials are discussed next, the Nernst equation being introduced and used. New chapters on Balancing Redox Equations and Chemical Equivalence appear here. Throughout, examples of various types of quantitative calculations are worked out in detail, step by step.

The last third of the book is devoted to descriptive chemistry, the elements being discussed by families, representative elements first, transition elements and the inert gases last. Liberal use is made of oxidation potential data and of tables presenting comparative properties of the elements. A chapter on Complex Ions, dealing with instability constants, structure, and magnetic properties comes early in the discussion of the metals.

A feature of the book which adds greatly to its usefulness is the extensive set of exercises given at the ends of the chapters. These are divided into Questions, Basic Problems, and Advanced Problems, and would appear to challenge students of a wide range in capability.

Despite the care and thoughtfulness evidenced in the organization and writing of this book, it is inevitable that there should be some items to which exception may be taken: The orbital diagram for ethylene, Fig. 9.8, is unclear and indicates a nonplanar structure for this molecule. On p. 311, as an alternative explanation for the behavior of HCl in water, occurs the statement, "It may also be argued that since. . . the water molecule is tetrahedral, the O—H bond between H_2O and HCl is an sp^3 hybrid bond. Since hybridization results in increased bond strength, the O—H bond will be stronger than the nonhybridized H—Cl bond, so the latter will break." One may quarrel, too, with the statements that "*oxidation always involves loss of electrons while reduction always involves gain of electrons*" (p. 367).

In the reviewer's opinion, this book would be admirably suited for use in a substantial introductory college course designed for students who have had some high school chemistry. Able students without such background could use it profitably, too, but might require some supplementing of the first chapter on basic concepts. In any case, the book is designed to *teach* as well as to generate interest.

University of Kansas
Lawrence

Radiation Effects on Organic Materials

Edited by *Robert O. Bolt* and *James G. Carroll*, California Research Corp., Richmond. Academic Press, Inc., New York, 1963. xv + 576 pp. Figs. and tables. 16.5 × 24 cm. $13.50.

The book is not what its title indicates, namely a treatise on the effect of nuclear radiation on organic matter, but a very thorough and up-to-date treatment of the radiation damage sustained by such organic materials as are commonly used in the construction and operation of nuclear reactors. Because of its high degree of specialization and the restriction to special groups of organic materials, it will not appeal to the student or general scientist as a source of information on a very important subject, but constitutes a most valuable source of information for the specialist, the nuclear scientist or engineer.

The two introductory chapters on Interaction of Radiation with Matter and on Mechanisms of Chemical Effects of Ionizing Radiation written by Amos S. Newton are well written, very concise, and instructive; so is the third introductory chapter on Radiation Chemistry of Pure Compounds, written by the editors. The

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

following chapters, all written by eminent experts in their respective field, deal with polymers, plastics, elastomers, coolants, lubricants, adhesives, coatings, dielectric fluids, fuels and shielding materials, coal, wood, and explosives.

While all the discussions in the above-mentioned chapters deal with damaging or deteriorating effects of radiation, the large field of radiation chemistry and radiation-induced beneficial transformation of matter is presented in the last chapter of the book on 10 pages. This is, of course, inadequate to cover the subject matter.

In spite of this high degree of specialization and compartmentalization which makes frequent repetitions unavoidable, the book fulfils two very useful and necessary functions. In the first place it makes comparisons between the data easier by adopting throughout the book a uniform terminology and expressing the most important radiation unit, namely that of absorbed dose, in rads as defined by the International Commission on Radiological Units as 100 ergs per gram of material. And secondly it makes much material accessible otherwise not available through the conventional scientific and technical publications up to 1962.

For these reasons the book will serve as a comprehensive, reliable, and up-to-date reference handbook for all those who need in their work such a well-ordered compilation of data. And the non-specialists who may peruse the volume will get an idea of the great intricacies involved in selecting and protecting materials that are exposed to all kinds of nuclear radiation.

FRANCIS JOSEPH WEISS
Library of Congress
Washington, D. C.

Advances in Physical Organic Chemistry. Volume 1

Edited by *V. Gold*, University of London, England. Academic Press, Inc., New York, 1963. xv + 443 pp. Figs. and tables. 16 × 23.5 cm. $13.

This is the first volume of a new series which aspires to become a recognized medium for the publication of authoritative reviews in physical organic chemistry. This field includes two general areas: studies of reactivity and reaction mechanisms, and studies of physical properties and molecular structure. Although two important books called "Physical Organic Chemistry" are concerned mainly with the former area, Dr. Gold stresses that his series is intended to cover the whole field.

The first three of six chapters of the present volume concern reactivity and mechanisms, and the last three deal with physical properties and structure. Though this reviewer's research is mainly in the former area, he must acknowledge that physical properties and structure have won the field insofar as this book is concerned.

The first chapter, Entropies of Activation and Mechanisms of Reactions in Solution, by W. F. Sager and Stanley L. Long, is disappointing mainly because it is too short. Though it touches on a number of important points, it frequently offers but a few sentences of general comment and then directs the reader to another article or book.

A Quantitative Treatment of Directive Effects in Aromatic Substitution, by L. M. Stock and H. C. Brown, is 120 pages long. Brown's extension of the Hammett $\rho\sigma$ relationship to electrophilic aromatic substitution and certain side chain reactions is presented, but nucleophilic and radical substitutions are ignored. A wealth of data is neatly set forth in tables, but the discussion is tedious and tends to overstate the achievements of Brown and his coworkers.

A. I. Shatenshtein's Hydrogen Isotope Exchange Reactions of Organic Compounds in Liquid Ammonia is valuable because it summarizes a series of researches published mainly in Russia. Perhaps because of a too literal translation, the chapter does not read easily. It seems wordy.

Planar and Non-Planar Aromatic Systems, by G. Ferguson and J. M. Robertson, is a beautifully organized presentation first of methods for detecting deviations from coplanarity, and then of information about a host of specific systems or compounds.

The Identification of Organic Free Radicals by Electron Spin Resonance, by M. C. R. Symons, is a careful and thorough review of this timely subject.

The Structure of Electronically Excited Organic Molecules, by J. C. D. Brand and D. G. Williamson, is mainly concerned with the dozen or so stable organic molecules whose spectra have been analyzed sufficiently to characterize at least one electronically excited state. The chapter is written in the language of the spectroscopist, to which a good introduction is provided.

Every college library should have this book. Purchase is also recommended to individual chemists interested in the field. It is hoped that future volumes will maintain a standard such that the latter statement can be conscientiously repeated.

JOSEPH F. BUNNETT
Brown University
Providence, Rhode Island

Quantitative Organic Analysis via Functional Groups

Sidney Siggia, Olin Mathieson Chemical Corporation, New Haven, Connecticut. 3rd ed. John Wiley and Sons, Inc., New York, 1963. xii + 697 pp. Figs. and tables. 15.5 × 23.5 cm. $19.

The third edition of this book has been lengthened to 697 pages and, therefore, should be reviewed as a new book and not merely as a revision of the second edition. (THIS JOURNAL 31, 558 [1954]).

Dr. Siggia has a reputation for doing a thorough job and this volume is no exception. Each chapter contains a brief historical summary, a discussion of each chemical reaction used for the group, the working procedures presented in full detail, and suitable trace methods for low concentrations. It is pointed out properly that most methods given can be conducted on a microscale if desired.

This volume will receive some criticism because reaction mechanisms and the like are minimized. However, the author indicates in both the preface and the introduction that this is a working book and not a theoretical book.

On the other hand, this volume has much to make its use a necessity in a laboratory doing organic analysis. All of the methods included have been tested in the author's laboratory and as a result minor variations from the literature are to be found. Any competent technician should be able to do the determinations. The chapter on the use of reaction rates to analyze mixtures is a good practical treatment with understandable examples and should become a part of every undergraduate course in analytical chemistry. The chapter on Techniques and Reasoning is a lucid account of the steps in problem-solving.

In a book of this size minor errors are almost impossible to eliminate, so an occasional "burette" and "$Na_2S_2O_2$" for $Na_2S_2O_3$ were not unexpected. The author states that he has selected the methods for utility in his laboratory so some chemists will be surprised to find their contributions overlooked. The printing and binding are excellent.

Most academic and industrial libraries will require this volume, but the price will make it borderline for individuals.

K. G. STONE
Michigan State University
East Lansing

The Structures and Reactions of Organic Compounds: An Introduction

M. F. Grundon and *H. B. Henbest*, both of Queen's University, Belfast, Ireland. Prentice-Hall, Englewood Cliffs, New Jersey, 1962. viii + 208 pp. Figs. and tables. 14.5 × 23.5 cm. $6.

The authors have attempted to present in two hundred pages "the basic ingredients of a modern course in organic chemistry." The problems of choice of topics and how extensively to cover these topics have been handled in a reasonable way in this text. Much more treatment of mechanisms is included than is usual in a book of this type. All too often, however, brevity has been achieved by compression instead of by omission, with the result that some sections would be harder for the student to read than would be corresponding sections in a more extensive text. The difficulty is compounded by the authors' habit of using, without explanation or cross reference, technical terms (such as ester and amine) which they have not yet defined. The literary style sometimes causes further difficulty, as on page 57: "The name *aldehyde* is derived from the words '*al*cohol *deh*ydrogenation,' as acetaldehyde, the first aldehyde to be dis-

NOTICE TO AUTHORS

1. **Forwarding Address.** Papers intended for publication in the JOURNAL OF CHEMICAL EDUCATION should be submitted to WILLIAM F. KIEFFER, *Editor*, College of Wooster, Wooster, Ohio.

2. **Manuscript.** The manuscript submitted should not have been published elsewhere. The work of the editorial office is facilitated and better service is assured the author when **duplicate copies** (the original and a carbon) are submitted. Typing of both text and references should be **double-spaced** with 2–3 cm margins. The title of the article should be followed by the name and business or institutional address of the author. If the paper has been presented at a meeting, a footnote giving name of the society, date, and occasion should be included but should not be numbered. Purple hectograph copy and mimeographed copy are not acceptable. The usual editorial customs, as exemplified in the most recent issue of the JOURNAL, should be followed as closely as possible.

Galley proof of each article will be submitted to the author. This proof should be carefully corrected and returned promptly to the *Editor's Office*. Page proof will not be submitted.

3. **References and Footnotes.** In historical and biographical articles and in papers containing no more than six literature references it is desirable that the references be handled as footnotes. Such references should be designated by superior numbers,[1] and the footnotes should be placed at the end of the text in numerical order.

References to explanatory notes such as change of author address, author acknowledgments, etc., should be designated beside the author's name by superior numbers in sequence with other footnotes in the article.

In articles of the scientific review type each reference to the literature should be designated by a number, in italics (indicated in a typescript by a single underline) and enclosed in parentheses, corresponding in size with the body of the text and set in the line of reading matter, i.e., (*6*). References are to be assembled, arranged numerically, and placed at the end of the article under the heading, Literature Cited. The numbers in parentheses are to be placed flush with the margin and if the reference exceeds one line, the succeeding line or lines should be indented. **The list of references should be typed, double-spaced.**

When specific citations of previous literature are not made but when it seems desirable to append a general bibliography, it is preferable that arrangement be made alphabetically on the basis of authors' or senior authors' names.

A *reference to a periodical* should include, in the order named: (1) author's name, (2) name of periodical (use of standard abbreviations designated in the "List of Periodicals Abstracted by *Chemical Abstracts*"), (3) volume number, (4) page (give exact page number at which the point cited is to be found, or if the entire article is the reference, give the page numbers inclusive) and (5) date of publication.

Examples:

(1) IHRIG, J. L., AND CALDWELL, R. G., J. CHEM. EDUC., 32, 320 (1955).

(2) GOWING, D. P., AND LEEPER, R. W., *Science*, 122, 1267 (1955).

A *reference to a book* should include, in the order named: (1) author's name, (2) title of book (enclosed in quotation marks), (3) edition, if more than one, (4) name of publisher, (5) address of publisher, (6) date of publication, (7) volume number, (8) pages (give exact page number at which the point cited is to be found).

Example:

(1) LATIMER, WENDELL, M., AND HILDEBRAND, JOEL H., "Reference Book of Inorganic Chemistry," 3rd ed., The Macmillan Co., New York, 1951, p. 110.

4. **Illustrations.** Not all articles lend themselves to illustration, but articles which do should be accompanied by as many pertinent illustrations as possible. The best possible selection of illustrations available will be made by the editorial staff. As a rule, apparatus, particularly if complicated, is best presented by means of line or working drawings. Photographs are sometimes sufficient, however. When both can be obtained, it is generally desirable to include both with the manuscript. Unless lettering can be done by one of the mechanical devices it should be in pencil only.

Photographs should have a gloss finish and should be at least postcard size—larger, if possible. Only prints which are unblurred and which show sharp contrast between light and dark areas can be satisfactorily reproduced. Authors should exercise scrupulous care in crediting photographs which require credit.

Line drawings should be carefully prepared in *black India ink* on plain white drawing paper, blue tracing cloth, or blue-lined coordinate paper twice or three times the size desired in the printed cut; it is convenient, when permitted by the scale required, to have them the size of the manuscript.

For *graphs* coordinate paper should be printed in *blue* only, with the important coordinate lines ruled over in black; the black-ruled square should in general not be less than ten millimeters on a side; the lines of the curves should be the heaviest, except the axes; points on the curves should be indicated by true circles, not crosses. All lines, legends, numbers, and letters which cannot be set in type at the margin of the cut but most constitute a portion of the cut itself are to be so proportioned that they will be clearly legible in the cut. The numbering of the coordinate axes, the number of the figure, and any necessary explanations of the figure should be printed in pencil in the margin of the sheet, as they are usually set up in type rather than reproduced from the drawing. Typewritten designations are not black enough to reproduce satisfactorily. Where lettering cannot be done adequately, designations left in pencil can be taken care of by the printer.

Tables should be placed on separate sheets, with a marginal notation on the manuscript to indicate preferred location.

All photographs, line drawings, and tables should be provided with self-explanatory titles or legends. Each illustration should be marked in pencil on the margin with the name of the author and the title of the article to which it refers.

Authors are invited to examine the series of articles by E. M. Hoshall entitled "Chemical Drawing" ["I. Fundamentals of chemical drawing," J. CHEM. EDUC., 11, 21–3 (1934); "II. Conventional representation of materials and equipment," 23–7; "III. Arrangements of drawings," 154–8; "IV. Charts, graphs, and diagrams," 235–41; "V. Photographs," 546–50].

5. **Reprints.** A reprint price list is printed on the reverse side of the order slip which accompanies galley proofs. Reprints are delivered approximately one month after articles appear.

ANNUAL INDEX
Journal of Chemical Education
Volume 40, 1963

The annual index for Volume 40 of the Journal of Chemical Education is divided into several parts. Authors are listed in three sections: authors of articles, books reviewed, and letters to the editor. The subject index includes both subjects and titles to articles; the books reviewed are listed in a separate section. The principal subject entries are distinguished from titles by printing the former in italics. Portraits, including medals, are indicated by (P), letters to the editor by (L), errata by (E).

Educational programs
Review—SAMA award address 460
Effect of chloride ion on precipitation of cadmium sulfide. Tested demonstration. A313
Effective teaching of organic chemistry. FRANK L. LAMBERT 173
Electrical discharges in preparative inorganic chemistry, Uses of. ALAN G. MASSEY 311
Electrochemistry
Galvanic cells experiment 363
Magnesium cell demonstration 43
Tantalum electrodes 320
Electrodes for depositions, Using tantalum and platinum-clad tantalum. EUGENE D. OLSEN, R. F. EAKIN, AND W. J. BLAEDEL 320
Electrolysis of sodium through glass. Tested demonstration A313
Electrolytes
Hydrated hydronium 637
Electronic spectra of transition metal complexes. RICHARD L. CARLIN 135
Electrophoretic study of synthetic food dyes. M. H. ANWAR, S. NORMAN, B. ANWAR, AND P. LAPLACA 537
Electrostatic view of chemical forces, A classical. H. H. JAFFÉ 649
Elementary processes, A course in kinetics based on. RICHARD M. NOYES 584
Elements, chemical, Naming in Chinese. RUFUS SUTER 44
CHANG, J. C. (L) 388
TUNG, CHEN TA (L) 388
WU, CHISUNG (L) 388
Emission Spectroscopy. Topics in Chemical instrumentation. STEPHEN E. WIBERLEY AND HERBERT H. RICHTOL A927
Enamines, The chemistry of. JOSEPH A. WEST 194
Energies, Intrinsic bond. S. SIEGEL AND B. SIEGEL 143
Energy relations in teaching organic chemistry. NORMAN L. ALLINGER 201
Enrichment program in chemistry for the advanced high school student. GEORGE L. JONES, JR. 605
Entropy data, Heat of vaporization of I_2 using absolute: A physical chemistry experiment. FRED E. STAFFORD 249
Equilibria in general chemistry, Heterogeneous. LEONARD C. GROTZ 479
Equilibrium, chemical, An experimental program on. R. N. REUSCH AND P. H. CARNELL 27
Equilibrium constant, Static and kinetic measurements of an: A physical-inorganic chemistry experiment. DOYLE BRITTON AND Z Z. HUGUS, JR. 607
Equilibrium study: A photometric formation of monothiocyanatoiron(III). RICHARD W. RAMETTE 71
Equilibrium, Temperature dependence of: A first experiment in general chemistry. BRUCE H. MAHAN 293
Erratum: Multicenter and Assisted Mechanistic Pathways (*cf.* THIS JOURNAL, 40, 185 (1963)) 326
Erratum: The Cesium Ratio (*cf.* THIS JOURNAL, *39*, 536 (1962)) 26
Error, Theoretical titration: In potentiometric, asymmetrical precipitation titrations. HOWARD L. CHRISTOPHERSON 63
Errors, Calculating titration. JAMES N. BUTLER 66
Errors in the determination of association constants, Random and systematic. R. A. PASTERNAK AND A. P. BRADY 254
Esterification for the introductory organic laboratory course: A modified Dean-Stark trap. W. H. PUTERBAUGH, C. H. VANSELOW, K. NELSON, AND E. J. SHRAWDER 349
Ether, methyl ethyl, Student preparation and manipulation of a gas. JOSEPH CASANOVA, JR. 41
Evaluating a chemistry program. RENEÉ G. FORD 16
Evaluation of the Toledo chemistry placement examination, An. NELSON W. HOVEY AND ALBERTINE KROHN 370
Evans, Joseph (P) 108
Evaporator for heat sensitive compounds, Simple. CHARLES R. BEGEMAN 427
Evaporator, Vacuum distillation with an all glass rotary. M. BENTON NAFF AND WILLIAM SPECTOR 327
Examinations
Letter 50
Objective tests 107
Exothermicities of compounds to chemical bonding, Relationship of. BERNARD SIEGEL 308
Experiment with galvanic cells, An: For the general chemistry laboratory. CLYDE R. DILLARD AND PATTY HALL KAMMEYER 363
Experimental laboratory course, An. MELVIN S. NEWMAN AND PAUL G. GASSMAN 203
Experimental program on chemical equilibrium, An. R. N. REUSCH AND P. H. CARNELL 27
Experiments in radiochemistry, Criteria for. HERBERT M. CLARK 618
Extraction of cobalt(II) complexes: A radiochemistry experiment. JOHN C. SHEPPARD AND REILLY C. JENSEN 33
Extraction, successive, of the heavier phase, Separatory funnel for. ROBERT J. HANRAHAN 69
Eye-dropper bulbs, Uses for rubber. MEYER M. MARKOWITZ AND DANIEL A. BORYTA 482

Flash of genius, The. ALFRED B. GARRETT
12. Radioactive tracers: George de Hevesy 36
13. Carbon-14 dating: Willard F. Libby 76
14. The positron: C. D. Anderson 123
15. Discovery of insulin: Frederick Banting 211
16. Quantum theory: Max Planck 262
17. Discovery of the transistor: W. Shockley, J. Bardeen, and W. Brattain 302
Flowing clock reactions. M. L. HAGGETT, PETER JONES, AND K. B. OLDHAM 367
Fluidized-solid constant temperature bath, A small. HARRY E. WEIR AND T. F. RUTLEDGE 425
Foam fractionation, Separation of surface active compounds by. R. M. SKOMOROSKI 470
Fog formation. Tested demonstration A477
Food dyes, Electrophoretic study of synthetic. M. H. ANWAR, S. NORMAN, B. ANWAR AND P. LAPLACA 537
Forces, A classical electrostatic view of chemical. H. H. JAFFÉ 649
Formaldehyde clock reaction, The theory of the. PETER JONES AND K. B. OLDHAM. 366
Formation constants of a metal-anionic ligand system in dioxane-water. DAVID E. GOLDBERG 341
Formation of monothiocyanatoiron(III): A photometric equilibrium study. RICHARD W. RAMETTE 71
Freezing point observations on micellar solutions. ERIC HUTCHINSON AND FUMIKATSU TOKIWA 472
Freshman chemistry, Technical report writing in. NELSON MCKAIG, JR. 86
Freshman laboratory, Instrument for the: Magnetic stirrer. W. H. SLABAUGH 642
Friedel-Crafts alkylation. Textbook errors, 44. KENNETH L. MARSI AND SAMUEL H. WILEN 214
Fuller, E. C. (P) 223
Funnel, Separatory, for successive extraction of the heavier phase. ROBERT J. HANRAHAN 69

Galvanic cells, An experiment with: For the general chemistry laboratory. CLYDE R. DILLARD AND PATTY KAMMEYER 363
Galvanism?, Who discovered. EDWARD F. KOHMAN 655
Gas, A simple condensation isotherm for a hard sphere. FRED VASLOW 485
Gas chromatography demonstration apparatus, A. JOHN MCLEAN AND PETER L. PAUSON 539
Gas chromatography, Determining activity coefficients by: A physical chemistry experiment. SUSAN KENWORTHY, JAMES MILLER, AND D. E. MARTIRE 541
Gas chromatography, Terminology of A170
Gas—methyl ethyl ether, Student preparation and manipulation of a. JOSEPH CASANOVA, JR. 41
Gas saturation apparatus, A. PAUL SCHATZBERG 267
Gaseous species at high temperatures, Stable. BERNARD SIEGEL 304
Gases, The chemical behavior of ions in. J. L. FRANKLIN 284
Gelatin, Demonstrating the Weissenberg effect with. JAMES H. WIEGAND 475
General chemistry
Electrochemistry demonstration 43
Equilibrium experiment 293
Galvanic cell experiment 363
Kinetics symposium 573
Stereochemistry introduction 438
Teaching equilibria 479
General chemistry laboratory, A simple kinetics experiment for. W. H. CONE AND R. A. HERMENS 421
General chemistry, Placement in. VIRGINIA M. SCHELAR, ROBERT B. CLUFF, AND BERNICE ROTH 369
Genetically related radionuclides: Growth-decay studies of ThB-ThC. P. P. PAREKH AND M. SANKAR DAS 354
Geochemistry, Modern. W. S. FYFE 330
German chemical and atomic energy documentation centers. H. A. BUCH 82
Gibbs-Duhem equation
Letters in regard to (THIS JOURNAL, **39**, 527 (1962)) 225-8
Gibbs-Duhem equation, Duhem and the. DONALD G. MILLER 648
Gilmont, Roger (P) A491
Glass electrode *p*H meter using a vacuum tube voltmeter, A. HAROLD E. BROWER 85
Glass, Recent developments in. ROBERT H. DALTON 99
Glossary, Chromatographic. Topics in chemical instrumentation. S. Z. LEWIN, *Editor* A167
Gordon, Saul (P) A87

Instruction, programed: Symposium 11
Instrument for the freshman laboratory: Magnetic stirrer. W. H. SLABAUGH ... 642
Instrumentation, A modular approach to chemical. EDWARD N. WISE 73
Instrumentation for particle size analysis. Topics in chemical instrumentation. S. Z. LEWIN.
Part 1 ..... A257
Part 2 ..... A349
Part 3 ..... A423
Insulin, Discovery of: Frederick Banting. The flash of genius, 15. ALFRED B. GARRETT 211
Intrinsic bond energies. S. SIEGEL AND B. SIEGEL 143
Intrinsic programs. JESSE H. DAY 14
Inverted mirror image, An. SCOTT L. KITTSLEY 558
Iodide ion as a qualitative reagent: Detection of nitrite and sulfite. ARMINE D. PAUL AND JOHN A. GIBSON, JR. 417
I_2 using absolute entropy data, Heat of vaporization of: A physical chemistry experiment. FRED E. STAFFORD 249
Ion combination reactions, Potentiometric titration curves for simple. JAMES A. GOLDMAN 519
Ion exchange method, Removal of hardness and deionization of water by the. Tested demonstration A987
Ion exchange resins, Dissolving difficulty soluble salts with chelating. RONALD RICH 414
Ionic and molecular halides of the phosphors family. ROBERT R. HOLMES ... 125
Ionic crystal structures, Standard. WILLIAM G. GEHMAN 54
Ionic strength effects, A class study of: The dissociation quotient of bromcresol green. RICHARD W. RAMETTE 252
Ions, aqueous, and other chemical species, Conventions defining thermodynamic properties of. RICHARD M. NOYES 2
Ions in gases, The chemical behavior of. J. L. FRANKLIN 284
Ireland, Scientific education in. J. A. SHUFLE 88
Iron tricarbonyl complexes, Chemistry of diene-. R. PETTIT, G. EMERSON, AND J. MAHLER 175
Isoelectric point of a protein, Viscometric determination of the. JOHN E. BENSON 468
Isomerism in aliphatic chains, Models illustrating rotational. H. J. G. HAYMAN 208
Isomorphism
Minerals and chemistry 512
Isotherm for a hard sphere gas, A simple condensation. FRED VASLOW 485
Isotopes, Hydrogen. Tested overhead projection series. HUBERT N. ALYEA .. A460

Jordan, Joseph (P) A5

Kamen, Martin D. (P) ....234, 238, May cover
Kinetics
Arsenate iodide 607
Coupled systems demonstrations 395
Order evaluation 269
Kinetic equation for ideal gas pressure, Rigorous derivation of the. M. W. C. DHARMANWARDHANA AND K. G. A. DHARMAWARDANE 318
Kinetic measurements of an equilibrium constant, Static and: A physical-inorganic chemistry experiment. DOYLE BRITTON AND Z Z. HUGUS, JR. 607
Kinetic studies below room temperature, A reaction vessel for. G. C. LALOR ... 597
Kinetic theory description of transport phenomena, A unified. ELDON KNUTH 486
Kinetics, A laboratory program in chemical. JAMES E. FINHOLT 589
Kinetics based on elementary processes, A course in. RICHARD M. NOYES 584
Kinetics— early and often. J. A. CAMPBELL 578
Kinetics experiment for general chemistry laboratory, A simple. W. H. CONE AND R. A. HERMENS 421
Kinetics experiment for the physical chemistry laboratory. A. ROBERT D. WHITAKER 264
Kinetics for the undergraduate: Symposium. EDWARD L. KING 573
Kinetics in laboratory and classroom, Chemical. ROBERT E. CONNICK 587
Kinetics in the study of organic reaction mechanisms. ROBERT H. DEWOLFE .. 95
SONG, PILL-SOON (L) 555
Kinetics, Polymerization, and viscometric characterization of polystyrene: A physical chemistry experiment. J. H. BRADBURY 465
Kjeldahl apparatus, A "direct attachment." J. STOCK AND A. V. DETHOMAS 87

Laboratory course, An experimental. MELVIN S. NEWMAN AND PAUL G. GASSMAN 203
Laboratory cylinder-mill for small samples. M. D. SCHLESINGER, S. NAZARUK, AND LESLIE REGGEL 546
Laboratory experiments
Activity coefficients by VPC 541
Alkali metal-water reactions 633

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Analytical of inorganic mehanism 151
Analytical organic 93
Arsenate iodide kinetics 607
Blue bottle kinetics 573
2-Bromonaphthalene synthesis 544
Calculations for I_2 from spectra 249
Carbon-14 in organic chemistry 206
Cobalt(II) complexes by radioisotopes ... 33
Criteria for radiochemistry 618
Diels-Alder reaction 40, 543
2,4-Dinitroaniline synthesis 545
Diphenylamine synthesis 346
Dissociation pressures 611
Electrophoresis 537
Equilibrium study 71
Esterification 349
Foam fractionation experiment 470
Formation constants 341
Freezing point of micellar solutions 472
Galvanic cells 363
HCl spectrum 245
Inorganic complexes 476
Ion combinations by potentiometry 519
Isopropyl ether hazard 469
K_{diss} from bromcresol green 252
$KClO_3$ decomposition ..... 78, (L)94, (L)94
Kinetics at Berkeley 587
Kinetics of complex ion dissociation 264
Kinetics program 589
Lasers for physical chemistry 338
Measuring water activity 419
Methyl ethyl ether synthesis 41
Neptunium chemistry 35
NMR spectra 358
Organic 203
Organic analysis 93
Organic synthesis 174
Oxidation of mercaptans 39
Pinene organics 347
Plant pigments by thin layer chromatography 29
Polaroid camera for radioautography 243
Polymers 465
Preparations of phosphors ..... 362, (L)667
Protein isoelectric point 468
Quantitative paper chromatography 408
Radiochemistry growth-decay 354
Rare earths 433
Semimicro Rast method 422
Simple kinetics 421
Spectrograph 452
Stereochemistry of (−) menthol 205
Stoichiometry 344
Thallium(I) bromide solubility by radioisotopes 34
Thermodynamics for general chemistry .. 293
Thin layer chromatography 531, 534, 536
Tl(I)Br solubility by radioisotopes 34
Laboratory program in chemical kinetics, A. James E. Finholt 589
Lantern slides, The preparation of inexpensive. William H. R. Shaw and John N. Aronson 483
Rubin Battino (L) 667
Lanthanides, The lighter: A laboratory experiment in rare earth chemistry. George B. Kauffman, Lloyd T. Takahashi, and R. C. Vickery 433
Laser experiments in undergraduate physical chemistry laboratory. Richard G. Layton and Edward M. Eyring .. 338
Lead, Dating of uranium minerals by the specific radioactivity of. A. W. Fairhall 626
Leaf pigments, Thin layer chromatographic separation of: A rapid demonstration. Charles Rollins 32
Lecture demonstrations
Alkali metal-water reactions 633
Blue bottle kinetics 578
Clock reaction theory 366
Coupled systems 395
Electrophoresis of food dyes 537
Flowing clock reactions 367
Gas chromatography 539
Inexpensive slides ..... 483, (L)667
Magnesium cell 43
Maxwell's demon demonstrator 49
Thin layer chromatography 531, 534, 536
Weissenberg effect 475
Leicester, Henry M. (P) ..... 108, March cover
Libby, Willard F.: Carbon 14-dating. The flash of genius, 13. Alfred B. Garret 76

Research publications ..... (L)228
Ligand system in dioxane-water, Formation constants of a metal-anionic. David E. Goldberg 341
Lighter lanthanides, The: A laboratory experiment in rare earth chemistry. George B. Kauffman, Lloyd T. Takahashi, and R. C. Vickery 433
Liquids, Significant structure theory of. Henry Eyring and R. P. Marchi 562
Low temperature zone refining apparatus. Morris Zief, Hollister Ruch, and Charles H. Schramm 351
Luminescent compounds, i.e., phosphors. Tested demonstrations A49

Magnesium cell for demonstration. Prem Behari Mathur and Nityanandan J. Paul 43
Magnetic stirrer: Instrument for the freshman laboratory. W. H. Slabaugh 642
Manometer, A simple closed end. Elmer R. Trumbull 350
Mass spectrometry
Ions in gases 284
Maxwell's demon demonstrator. M. V. Sussman 49
Measurement, Micrometric methods of volume. Topics in chemical instrumentation. Roger Gilmont A491
Measuring temperature in a closed rotating flask, Device for. Eugene K. Lubbs .. 200
Mechanisms, Inorganic reaction, by volumetric analysis: Oxidation of iodide ion. G. J. Moody and J. D. R. Thomas 151
Mechanisms, Kinetics in the study of organic reaction. Robert H. De Wolfe 95
Song, Pill-Soon (L) 555
Mechanisms, 2. Reactions and: Cyclobutane chemistry. Armin Wilson and David Goldhamer 599
Mechanistic pathways in the reactions of organometallic compounds, Multicenter and assisted. Raymond E. Dessy and Frank Paulik ..... 185, (E)326
Mendeleev have predicted the existence of XeF_4?, Would. Roland Ward 277
Menthol, The stereochemistry of (−): An organic laboratory experiment. Harmon C. Dunathan 205
Mercaptans to disulfides, A convenient synthetic technique to oxidize. T. J. Wallace, W. Bartok, and A. Schrieshiem 39
Metal-anionic ligand system in dioxane-water, Formation constants of a. David E. Goldberg 341
Method for determining order of a reaction. Howard K. Zimmerman 356
Methyl ethyl ether, Student preparation and manipulation of a Gas. Joseph Casanova, Jr. 41
Micellar solutions, Freezing point observations on. Eric Hutchinson and Fumikatsu Tokiwa 472
Micrometric methods of volume measurement, Topics in chemical instrumentation. Roger Gilmont A491
Microscale reactions, High pressure techniques for. Richard P. Rhodes 423
Microscope slides, TLC on: An organic chemistry experiment. M. Benton Naff and Anna S. Naff 534
Miller, William Allen (P) 612
Miller, William Allen: Pioneer stellar spectroscopist. Fred Trusell 612
Minerals, and chemistry, Crystals. Duncan McConnell and Frank H. Verhoek 512
Minerals by the specific radioactivity of lead, Dating of uranium. A. W. Fairhall 626
Mirror image, An inverted. Scott L. Kittsley 558
Mnemonics for thermodynamic equations. Edward T. Radley, Irwin Cohen, and Brother Thomas McCullough, CSC 261
Models
Atomic and molecular orbitals 256
Close packing 61
Conformational effects 28
Crystal forms 54
Modified Dreiding 204
Plastic Dreiding 457
Rotational isomerism 208
Tangent-sphere 446, 523
Models illustrating rotational isomerism in aliphatic chains. H. J. G. Hayman ... 208
Modern geochemistry. W. S. Fyfe 330
Modification of a vacuum desiccator. E. L. Head and D. Pavone 316
Modified Victor Meyer apparatus. G. Wilson Drake 606
Modular approach to chemical instrumentation, A. Edward N. Wise 73
Molecular distillation and vacuum sublimation, Apparatus for. Bernard Loev, Kenneth M. Snader, and Minerva F. Kormendy 426
Molecular models, Disc-shaped attachments for Dreiding-type. E. C. Kooyman ... 204
Molecular orbital structures, Rules for. Herbert Meislich 401
Molecular orbitals, Contour surfaces for atomic and. E. A. Ogryzlo and Gerald B. Porter 256
Molecular weights, Semimicro modification of the Rast method for determining. E. J. Cowles and M. T. Pike 422
Monoclinic sulfur crystals. Tested demonstration A477
Monothiocyanatoiron(III), Formation of: A photometric equilibrium study. Richard W. Ramette 71
More wealth from agriculture. William P. Ratchford and Norman E. Roberts 556
Moscow State University, Chemistry at. Richard E. Bozak 376
Multicenter and assisted mechanistic pathways in the reactions of organometallic compounds. Raymond E. Dessy and Frank Paulik ..... 185, (E)326

Significant structure theory of liquids. HENRY EYRING AND R. P. MARCHI 562
Simple approach to the second law, A. W. G. BRECK 353
Simple closed end manometer. ELMER R. TRUMBULL 350
Simple condensation isotherm for a hard sphere gas, A. FRED VASLOW 485
Simple evaporator for heat sensitive compounds. CHARLES R. BEGEMAN 427
Simple kinetics experiment for general chemistry laboratory, A. W. H. CONE AND R. A. HERMENS 421
Simple method for the preparation of 2,4-dinitroaniline. A. A. ASHTON 545
Simple model to illustrate conformational effects in acyclic molecules, A. A. TYE AND J. B. LAPIDUS 28
Simple preparations of phorphors. F. F. MIKUS 362
DE MENT, JACK (L) 667
Simple pressure stopcock, A. ROGER GILMONT 432
Simple separation of the group II-A sulfides. A. T. A. O'DONNELL 415
Simple thermoregulator, A. SAM KATZ 266
Slides, The preparation of inexpensive lantern. WILLIAM H. R. SHAW AND JOHN N. ARONSON 483
RUBIN BATTINO (L) 667
Small fluidized-solid constant temperature bath, A. HARRY E. WEIR AND T. P. RUTLEDGE 425
Sobering experience with isopropyl ether peroxide, A. IRWIN B. DOUGLASS 469
Sodium through glass, Electrolysis of. Tested demonstration A313
Solid state
Conduction and semiconduction 489
Organic semiconductors 547
Solubility of thallium(I) bromide, The: A radiochemistry experiment. JOHN C. SHEPPARD AND REILLY C. JENSEN 34
Solutions for qualitative analysis with a cation exchange resin, Preparation of. PAUL KEY, EDWARD SOHL, ROBERT TIEWS, AND CLARK BRICKER 416
Solutions, micellar, Freezing point observations on. ERIC HUTCHINSON AND FUMIKATSU TOKIWA 472
Solvay processes. Tested demonstration A535

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Some aspects of the history of chemistry in Russia. HENRY M. LEICESTER 108
Some experiments on the stoichiometry of reactions. H. R. TIETZE 344
Some models of close packing. RODNEY J. SIME 61
Soviet Union, Abstracting publication on chemical education in the. DAVID A. PATERSON 636
Spectra, Electronic, of transition metal complexes. RICHARD L. CARLIN 135
Spectrograph of moderately high resolution, An inexpensive. RALPH SCHOENBECK AND FREDERICK D. TABBUTT 452
Spectroscopy, Emission. Topics in chemical instrumentation. STEPHEN E. WIBERLY AND HERBERT H. RICHTOL A927
Spectrum of HCl, Vibration-rotation: A physical chemistry experiment. F. E. STAFFORD, C. W. HOLT, AND G. L. PAULSON 245
Sphere, Tangent-, models of molecules: I. Theory and construction. HENRY A. BENT 446
II. Uses in teaching 523
Sponsorship of committee on nuclear science —NAS-NRC. R. E. BALLOU 618
Stability of H_2Se, The thermal. Textbook errors, 42. KENNETH E. HAYES AND NADINE R. M. HAASE 149
Stable gaseous species at high temperatures. BERNARD SIEGEL 304
Standard ionic crystal structures. WILLIAM G. GEHMAN 54
Static and kinetic measurements of an equilibrium constant: A physical-inorganic chemistry experiment. DOYLE BRITTON AND Z. Z. HUGUS, JR. 607
Statistical thermodynamics
Theory of liquids 562
Stereochemistry in the terminal course. GORDON G. EVANS 438
Stereochemistry of (−) menthol, The: An organic laboratory experiment. HARMON C. DUNATHAN 205
Stirrer, Magnetic: Instrument for the freshman laboratory. W. H. SLABAUGH 642
Stoichiometry of reactions, Some experiments on the. H. R. TIETZE 344
Stopcock, A simple pressure. ROGER GILMONT 432
Strain energy, 1. Structure and. Cyclobutane chemistry. ARMIN WILSON AND DAVID GOLDHAMER 504
Structural chemistry
Benzene clathrate 646
Clathrates 643
Close packing models 61
Cyclobutane 504, 599
Electrostatic chemical forces 649
Graphite 117
Hydrogen bonds 598
Inert gas compounds 277
Ionic crystals 54
Molecular orbitals 401
Plastic Dreiding models 457
Solid state 489
Tangent-sphere models 446, 523
VSEPR theory 295
Structure theory of liquids, Significant. HENRY EYRING AND R. P. MARCHI 562
Structures, Rules for molecular oribital. HERBERT MEISLICH 401
Student and teacher, Both can benefit. JAY A. YOUNG 11
Student preparation and manipulation of a gas—methyl ethyl ether. JOSEPH CASANOVA, JR. 41
Sulfides, A simple separation of the group II-A. T. A. O'DONNELL 415
Sulfite, Detection of nitrite and: Iodide ion as a qualitative reagent. ARMINE D. PAUL AND JOHN A. GIBSON, JR. 417
Superoxides, The inorganic. A. W. PETROCELLI AND D. L. KRAUS 146
Surface active compounds by foam fractionation, Separation of. R. M. SKOMOROSKI 470
Survey, Report of a: The present and future of qualitative analysis. NELSON W. HOVEY 410
Symposia
Programed instruction 11
Kinetics for the undergraduate 573
Syntheses, Project, for organic laboratory courses. STANLEY C. BUNCE 174
Systematic errors in the determination of association constants, Random and. R. A. PASTERNAK AND A. P. BRADY 254

Tangent-sphere models of molecules, I. Theory and construction. HENRY A. BENT 446
II. Uses in teaching 523
Tantalum and platinum-clad tantalum electrodes for depositions, Using. EUGENE D. OLSEN, R. F. HAKIN, AND W. J. BLAEDEL 320
Teacher, and student, Both can benefit. JAY A. YOUNG 11
Teaching, chemistry, Programing as an effective aid to. G. R. BAKKER, O. T. BENFEY, AND W. J. STRATTON 18

BOOKS REVIEWED

TITLES

Absorption spectra and chemical bonding in complexes. C. K. Jørgensen A142
Absorption spectroscopy, Infrared. Koji Nakanishi 616
Advanced inorganic chemistry: A comprehensive text. F. Albert Cotton and G. Wilkinson 230
Advances in carbohydrate chemistry. Vol. 17. Melville L. Wolfrom and R. Stuart Tipson, *Editors* A597
Advances in chemical physics. Vols. 4 and 5. I. Prigogine, *Editor* 616
Advances in clinical chemistry. Vol. 5. Harry Sobotka, *Editor* A835
Advances in enzymology, Vol. 25 F. F. Nord, *Editor* A985
Advances in fluorine chemistry. Vol. 3. M. Stacey, J. C. Tatlow, and A. G. Sharpe, *Editors* A597
Advances in heterocyclic chemistry. Vol. 1. A. R. Katritzky, *Editor* 559
Advances in inorganic chemistry and radiochemistry. Vol. 4. H. J. Emeléus and A. G. Sharpe, *Editors* A238
Advances in mass sprectrometry. Vol. Z. R. M. Elliott, *Editor* A985
Advances in organic chemistry: Methods and results. Vol. 3. Ralph A. Raphael, Edward C. Taylor, and Hans Wynberg, *Editors* 444
Advances in petroleum chemistry and refining. John J. McKetta, Jr., *Editor*
Vol. 5 . . . . A320
Vol. 6 . . . . A532
Advances in physical organic chemistry. Vol. 1. V. Gold, *Editor* 670
Advances in protein chemistry. Vol. 17. C. B. Anfinsen, Jr., *et al.*, *Editors* A597
Advances in spectroscopy. Vol. 2. H. W. Thompson, *Editor* 170
Alliages métalliques. Vol. 20. Nouveau traité de chemie minérale. Paul Pascal, *General Editor*
Part 1 232
Part 2 . . . . A906
Analysis, Elementary quantitative. W. J. Blaedel and V. W. Meloche 614
Analysis including elementary instrumental analysis. A text-book of quantitative inorganic. Arthur I. Vogel A68
Analysis, Qualitative anion-cation: An interpretative laboratory text of semimicro procedure in basic college chemistry. Emil J. Margolis 390
Analysis, Standard methods of chemical. Vols. 2A and 2B, industrial and natural products and noninstrumental methods. Frank J. Welcher 560
Analysis, The electrochemical methods of: Electrochemical reactions. G. Charlot, J. Badoz-Lambling, and B. Trémillon 560
Analysis via functional groups, Quantitative organic. Sidney Siggia 670
Analytical chemistry, 1962: The proceedings of the international symposium held at Birmingham University, April, 1962. Philip W. West, A. M. G. MacDonald, and T. S. West, *Editors* 615
Analytical chemistry, Fundamentals of. Douglas A. Skoog and Donald M. West 614
Analytical chemistry, Handbook of. Louis Meites 560
Analytical chemistry, Ion exchange separations in. Olof Samuelson A669
Analytical Chemistry, The application of organic bases in. E. A. Ostroumov (D. A. Paterson, *Translator*) A318
Analytical chemistry, Treatise on. Part II, Analytical chemistry of the elements. I. M. Kolthoff, Philip J. Elvin G, and Ernest B. Sandell, *Editors*
Vols. 2, 9 . . . . A679
Vol. 8 . . . . A985
Analytischen chemie, Radioaktive isotope in der. L. M. Michejeva and N. B. Michejev (Hermann Jäger, *Translator;* Gisbert Grossman, *Editor*) 444
Anorganischen chemie, Gmelins handbuch der. 8th edition. E. H. E. Pietsch, *Editor.*
System 28: Calcium, part B, section 3 . . . 171
System 52: Chromium, part A, section 1 . 171
Application of organic bases in analytical chemistry, The. E. A. Ostroumov (D. A. Paterson, *Translator*) A318
Atomic-absorption spectrophotometry. W. T. Elwell and J. A. F. Gidley A54
Atomic and molecular structure, Vol. 1. Comprehensive biochemistry. Marcel Florkin and Elmer H. Stotz, *Editors.* A674
Atomic structure and bonding: A basic systems program. Charles R. Dawson, *Editor* 500
Atoms and molecules, Orbitals in. Chr. Klixbüll Jørgensen 231

Bacteria, Pentose metabolism in. B. L. Horecker A906
Basic chemistry problems for high school. John W. Sulcoski and Stephen Rituper 616
Basic concepts of nuclear chemistry. Ralph T. Overman 499
Basic experimental organic chemistry. James Cason and Henry Rapoport . . 106
Basic principles and calculations in chemical engineering. David M. Himmelblau. A322
Biochemical analysis, Methods of. Vol. II. David Glick, *Editor* A835
Biochemical applications of gas chromatography. H. P. Burchfield and Eleanor E. Storrs 105
Biochemical frontiers in medicine. Harris Busch, *Editor* A598
Biochemistry, Comparative. A comprehensive treatise. Vol. 4. Constituents of life, Part B. Marcel Florkin, and Howard S. Mason, *Editors* A316
Vol. 5. Constituents of life, Part C A985
Biochemistry, Comprehensive. Marcel Florkin and Elmer H. Stotz
Vol. 1. Atomic and molecular structure. A 74
Vol. 2. Organic and physical chemistry . A226
Vol. 3. Methods for the study of molecules A674
Vol. 4. Separation methods A674
Vol. 7. Proteins, Part 1 . . . . A985
Vol. 9. Pyrrole pigments, isoprenoid compounds, phenolic plant constituents A681
Vol. 10 . . . . A681
Vol. 11. Water soluble vitamins, hormones, antibiotics A681
Biochemistry, Horizons in; Albert Szent-Györgyi dedicatory volume. Michael Kasha and Bernard Pullman, *Editors* A218
Biochemistry, Molecular. Edward M. Kosower 172
Biochemistry, Outlines of. Eric E. Conn and P. K. Stumpf A833
Biochemistry, Practical clinical. Harold Varley A834
Biological chemistry, Elements of general and: An introduction to the molecular basis of life. John R. Holum 441
Biological chemistry, Essentials of. James J. Fairley and Gordon L. Kilgour . . A900
Biological research, Physical techniques in. Vol. IV, Special methods. William L. Nastuk, *Editor* A673
Bonding and the geometry of molecules, Chemical. George E. Ryschkewitsch 441
Boranes, Borax to. Robert Gould, *Editor* A66
Borax to boranes. Robert Gould, *Editor*. A66

Calcium, part B, section 3, System 28. Gmelins handbuch der anorganischen chemie. 8th edition. E. H. E. Pietsch, *Editor* 171
Calculations, Basic principle and, in chemical engineering. David M. Himmelblau A322
Calculations, Chemical. Sidney W. Benson 499
Calculations in physical chemistry. B. W. V. Hawes and B. H. Davies A827
Carbohydrate chemistry, Advances in. Vol. 17. Melville L. Wolfrom and R. Stuart Tipson, *Editors* A597
Carbohydrate chemistry, Methods in. Vol. 1, Analysis and preparation of sugars. Roy L. Whistler and M. L. Wolfrom, *Editors* A394
Carbon compounds, Chemistry of. Vol. 5, Miscellaneous. General index. E. H. Rodd, *Editor* 444
Catalysis by metals. G. C. Bond A416
Chem Sources. 4th edition 172
Chemical bonding and the geometry of molecules. George E. Ryschkewitsch 441
Chemical calculations. Sidney W. Benson 499
Chemical dictionary, Dictionnaire de chimie: Fachwörterbuch der chemie: Jean Fouchier and Fernand Billet 336
Chemical engineering, Modern. Vol. 1, Physical operations. Andreas Acrivos, *Editor* A980
Chemical physics, Advances in. Vols. 4 and 5. I. Prigogine, *Editor* 616
Chemical thermodynamics, Elements of. L. K. Nash . . . . 51, (L) 168
Chemistry 1: Atomic structure and bonding: A basic systems program. Charles R. Dawson, *Editor*
Chemistry 1: Response book.
Chemistry 1: Teachers manual 500
Chemistry for the applied sciences. Katherine Blood Hoffman 498
Chemistry of carbon compounds. Vol. 5, Miscellaneous. General index. E. H. Rodd, *Editor* 444
Chemistry of organic fluorine compounds. Milos Hudlický A472
Chemistry of rhenium. K. B. Lebedev . . . A974
Chemistry of the lanthanides, The. Therlad Moeller A830
Chemistry problems. Joseph F. Castka . . 334
Chemists, Great. Eduard Farber, *Editor* A898
Chromatography. Erich Heftmann, *Editor* A63
Chromatography, Gas. D. Ambrose and Barbara Ambrose 104
Chromatography, Gas. Ernst Bayer 104
Chromatography, Gas. John H. Knox . . . 104
Chromatography, Gas-liquid: Theory and practice. Stephen Dal Nogare and Richard S. Juvet, Jr. 104
Chromium, part A, section 3, System 28. Gmelins handbuch der anorganischen chemie. 8th edition. E. H. E. Pietsch, *Editor* 171
Clathrate inclusion compounds. Sister Martinette Hagen A222

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Clinical biochemistry, Practical. HAROLD VARLEY A834
Clinical chemistry, Advances in. Vol. 5. HARRY SOBOTKA, *Editor* A835
Clinical chemistry: Principles and procedures. JOSEPH S. ANNINO A64
Collection of problems in physical chemistry. JIRI BARES, *et al.* (HELENA WATNEY, *Translator*) 502
College chemistry. G. BROOKS KING AND WILLIAM E. CALDWELL 559
Comparative biochemistry: A comprehensive treatise. Vol. 4, Constituents of life, Part B. MARCEL FLORKIN AND HOWARD S. MASON, *Editors* A316
Complex compounds, An introduction to the chemistry of. ALEKSANDER ABRAMOVICH GRINBERG; D. H. BUSCH AND R. F. TRIMBLE, JR., *Editors* (J. ROVTAR LEACH, *Translator*) 282
Complexes, Absorption spectra hand chemical bonding in. C. K. JORGENSEN A142
Comprehensive biochemistry. MARCEL FLORKIN AND ELMER H. STOTZ, *Editors*
Vol. 1. Atomic and molecular structure A674
Vol. 2. Organic and physical chemistry A226
Vol. 3. Methods for the study of molecules A674
Vol. 4. Separation methods A674
Vol. 5. Constituents of life, Part C A985
Vol. 7. Proteins, Part 1 ..... A985
Vol. 9. Pyrrole pigments, isoprenoid compounds, phenolic plant constituents A681
Vol. 10. ..... A681
Vol. 11. Water soluble vitamins, hormones, antibiotics A681
Conservation of energy, Historical roots of the principle of the. ERWIN N. HIEBERT A533
Coordination compounds, Infrared spectra of inorganic and. KAZUO NAKAMOTO. 501
Cosmochemical problems, Some. HAROLD C. UREY A980
Cytology, International review of. Vol. 14. G. H. BOURNE AND J. F. DANIELLI, *Editors* ..... A 598

Debye, Peter, Based on the Harvard lectures of: Topics in chemical physics. ALFRED PROCK AND GLADYS MCCONKEY 502
Developments in inorganic polymer chemistry. M. F. LAPPERT AND G. J. LEIGH, *Editors* A894

Announcing a New Serial Publication . . .

Survey of Progress in Chemistry

Edited by **ARTHUR F. SCOTT.**

Volume 1, November 1963, 341 pp., **$7.95**

Survey of Progress in Chemistry will provide an advanced and efficient mechanism of education for the non-specialist—chemistry teachers, students, and chemists—who must be informed of all current developments in areas of chemistry which are of general interest and importance. Although expository in nature, the articles will carry references to other reviews and important papers. Each volume will contain material chosen from the entire field of chemistry.

Contents:

Riley Schaeffer, New Research Tools of Chemists
Alan W. Searcy, High-Temperature Reactions
R. E. Rundle, The Implications of Some Recent Structures for Chemical Valence Theory
William F. Little, Metallocenes
Kenneth B. Wiberg, Oxidation-Reduction Mechanisms in Organic Chemistry
William P. Jencks, The Chemistry of Biological Energy Transfer
Rudolf M. Salinger, The Structure of the Grignard Reagent and the Mechanisms of Its Reactions
SUBJECT INDEX—AUTHOR INDEX.

Introduction to Modern Biochemistry

By PETER KARLSON
With a Foreword by **Adolf Butenandt**
Translated from the German by **Charles H. Doering**
1963, 434 pp., $10.00

Introduction to Modern Biochemistry provides a completely integrated guide to the established facts, dominant theories, and modern applications of biochemical research. The book is based on Professor Karlson's long teaching experience, and presents a uniquely dynamic approach to biochemistry in that biological significance is stressed.

The work reflects the modern emphasis on turnover and control mechanisms, and thoroughly covers the correlation and application of principles. Special stress is placed on theories that explain the chemical phenomena unique to life.

Chemical Applications of Infrared Spectroscopy

By C. N. R. RAO
December 1963, 681 pp., $19.50

This new book, on one of the most powerful techniques available for chemical analysis, presents the basic concepts, measurements, and techniques of infrared spectroscopy. It has been designed as a complete work on the chemical applications of infrared spectroscopy. In addition to discussing group frequencies, the book reviews the applications of infrared spectroscopy in certain specialized branches of study such as transition metal complexes, charge transfer complexes, polymers and proteins, adsorbed molecules, and the matrix isolation technique. It will serve as a text and reference book for students, technicians, and research workers.

Revision of a classic . . .

The Proteins

Composition, Structure, and Function

Second Edition

Edited by **HANS NEURATH**

Volume 1, November 1963, 665 pp., $22.00

***Subscription price, $19.50**

**Subscription price valid on orders for the complete set received before publication of the last volume.*

Volume 2, about 700 pp., in preparation
Volumes 3-4, in preparation

Reviews of the first edition:

". . . this invaluable series . . . will appeal to the expert and the beginner in proteins . . . it presents a unified, critical, authoritative, and up-to-date treatment of the whole subject . . ."
—*Science*

"Considered together, these four volumes will be referred to for many years, not only for all phases of the chemistry of those important macromolecules, but also for their biological properties and biological activities."
—*Journal of Chemical Education*

Contents of Volume 1

Albert Light and **Emil L. Smith,** Amino Acid Analysis of Peptides and Proteins
G. R. Tristram and **R. H. Smith,** Amino Acid Composition of Certain Proteins
Klaus Hofmann and **Panayotis G. Katsoyannis,** Synthesis and Function of Peptides of Biological Interest
Joseph S. Fruton, Chemical Aspects of Protein Synthesis
Robert E. Canfield and **Christian B. Anfinsen,** Concepts and Experimental Approaches in the Determination of the Primary Structure of Proteins
R. Cecil, Intramolecular Bonds in Proteins. I. The Role of Sulfur in Proteins
Harold A. Scheraga, Intramolecular Bonds in Proteins. II. Non-covalent Bonds

BURRELL "For Scientists Everywhere"

LABORATORY SHAKERS

amazingly realistic wrist action®

You control procedures from gentle to violent shaking and repeat any operation, exactly, at another time. Side clamps take bottles and Erlenmeyer flasks. Loads need not be balanced.

Heavy-Duty Model

This rugged flat-top unit shakes up to 40 Erlenmeyer flasks or bottles.

Exclusive Build-Up® Design

One basic unit adapts to any combination. You build-up with an 8 place flat-top and with side arms for 4, 12 or 16 flasks.

®Trademark Registered U.S. Patent Office

Cat. No.	Shaker	Price
75-765-16	Build-Up Wrist-Action Shaker, Size BT for 8 top and 8 side flasks	289.50
75-785	Burrell Heavy-Duty Shaker, Size 40 for 40 flasks—flat-top only	400.00
75-765-08	Build-Up Wrist-Action Shaker, Size T —for 8 top flasks	260.00
75-775-08	Build-Up Wrist-Action Shaker, Size BB —for 8 side flasks	239.50

For 115 volts, 60 cycle, one phase. Other voltages to order. Prices listed are F.O.B. Pittsburgh, Pa.

BURRELL CORPORATION
Scientific Instruments and Laboratory Supplies
2223 FIFTH AVENUE, PITTSBURGH 19, PA.

covered (in 1774), was obtained later by the dehydrogenation of alcohol."

The descriptive chemistry is generally accurate and adequate, although exception may be taken here and there, as in the statement that chloromethane is made by the reaction of an equimolar mixture of methane and chlorine when in fact a large excess of methane is used. Formic acid is described as being made from carbon monoxide and steam, when the important processes are two-step operations.

Minor and irrelevant points are sometimes included. For example, the color, boiling point, and method of preparation of ozone are given. Strain theory and conformation are not touched upon at all.

Problems of IUPAC nomenclature are not adequately handled. The student is given little help in the construction of IUPAC names; apparently he is supposed to learn by inference from examples. Unacceptable hybridization of IUPAC with other style names is found in names such as "1-butyl halides," "isobutene," "the eight isomeric pentanols," and in the phrase "there are two *n*-butanols."

The questions at the end of the chapters are few and unimaginative.

In short, while this book is chemically sound and modern in approach, it leaves something to be desired in the way of organization and polish.

FLOYD L. JAMES
Miami University
Oxford, Ohio

Elementary Solid State Physics

Charles Kittel, University of California, Berkeley. John Wiley and Sons, Inc., New York, 1962. xi + 339 pp. Figs. and tables. 15.5 × 23.5 cm. $8.75.

"Elementary Solid State Physics" is a judiciously edited version of "Introduction to Solid State Physics." The reviewer can find little quarrel with the choice of material for a beginning one-semester course in the physics of solids. All the essential parts and the flavor of "Introduction" have been retained and there is sufficient detail and references to the original literature to give depth to the treatment. The problems at the end of each chapter are often taken over unchanged, but the more difficult starred problems have not been included. Many of the derivations in the Appendix of "Introduction" have been omitted.

Considerable new material, including tunnel diodes, masers, and the strength of metal whiskers, has been included. Users of the second edition of "Introduction" may want to use this more up-to-date version at the cost of using a less sophisticated treatment.

In comparison with Azaroff's "Introduction to Solids" (reviewed in J. CHEM. ED., 38, 586 [1961]), "Elementary Solid State Physics" is much more mathemat-

WILEY BOOKS

Including INTERSCIENCE

KIRK-OTHMER ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY Second Edition—Volume 2

Editorial Board: HERMAN F. MARK, *Chairman, Polytechnic Institute of Brooklyn;* JOHN J. McKETTA, Jr., *The University of Texas; and* DONALD F. OTHMER, *Polytechnic Institute of Brooklyn. Executive Editor:* ANTHONY STANDEN, *Interscience Publishers.* This unrivaled library of information for the chemical industry is now being brought up to date. Volume 2 covers *Aluminum Compounds* through *Azo Dyes.* To be published in 18 volumes. An Interscience Book. Vol. 1 (*Abherents* through *Aluminum*): *1963. 990 pages.* Vol. 2: *1963. Approx. 960 pages. Subscription Price: $35.00 per volume. Single Volume Price $45.00.*

FRIEDEL-CRAFTS AND RELATED REACTIONS Volume 2: Alkylation and Related Reactions In two parts

Edited by GEORGE A. OLAH, *Dow Chemical Company of Canada Ltd.* This is the second volume of a four-volume treatise that gives comprehensive and critical coverage of one of the most important and versatile fields of organic chemistry. An Interscience Book. *1963. Part I: Approx. 685 pages. Part 2: Approx. 720 pages. Both parts: $50.00 (not sold separately).*
(Volume 1: General Aspects; 1963. 1031 pages. $29.50).

ORGANIC FUNCTIONAL GROUP ANALYSIS BY MICRO AND SEMIMICRO METHODS

By NICHOLAS D. CHERONIS, *Formerly Professor of Chemistry; and* T. S. MA, *Professor of Chemistry, Brooklyn College of the City University of New York.* A comprehensive treatise on micro methods for the determination of functional groups in organic compounds which includes thorough discussions of nearly 100 functional groups and presentation of over 50 experimental procedures. An Interscience Book. *1964. In press.*

ADMINISTRATION OF THE CHEMICAL ENTERPRISE

Editor and principal author: CONRAD BERENSON, *Bernard M. Baruch School of Business and Public Administration, City College of the City University of New York.* A basic, yet sophisticated exposition of the chemical industry's commercial and management structure. Among the topics covered are marketing, management, advertising, promotion, personnel, patent law, accounting and finance. An Interscience Book. *1963. 414 pages. $11.50.*

THE CHEMICAL INDUSTRY: Viewpoints and Perspectives

Editor and principal author: CONRAD BERENSON. A fascinating collection of authentic case studies that show how basic commercial principles and strategies are actually applied in today's chemical process industry. An Interscience Book. *1963. 426 pages. $10.00.*

PHYSICAL ORGANIC CHEMISTRY

By KENNETH B. WIBERG, *Yale University.* Designed as a text for a full-year graduate course, this book concentrates on the physical chemical aspects rather than the organic chemical aspects of organic chemistry. Emphasizing quantitative understanding of the material, the book gives a very detailed coverage of chemical bonding, spectra, equilibria, and kinetics. *1963. Approx. 600 pages. Prob. $10.75.*

ANALYSIS AND CHARACTERIZATION OF OILS, FATS, AND FAT PRODUCTS—Volume I

By H. A. BOEKENOOGEN, *Technical University Eindhoven, The Netherlands.* The first in a series of monograph collections covering important advances in the rapidly changing field of chemical analysis, Volume I includes a general description of those classical methods in fat analysis which are still valuable and a critical survey of techniques for analyzing the most essential fatty acid, linoleic acid, and other analytical methods. An Interscience Book. *1963. Approx. 350 pages. Prob. $12.00.*

AMERICAN CHEMICAL SOCIETY SYMPOSIUM ON MORPHOLOGY OF POLYMERS

Edited by T. G. ROCHOW, *American Cyanamid Company.* Includes the papers presented at a symposium held at Los Angeles, April 4–5, 1963. The symposium was organized so that the parameters of morphology, composition and properties are considered on four levels of *macromolecular organization.* The topics are macromolecular domains, morphology of surfaces, the crystalline phase, and the polyphase systems. (Journal of Polymer Science, Part C. POLYMER SYMPOSIA, No. 3). An Interscience Publication. *1963. Approx. 144 pages. Prob. $6.00.*

HIGH SPEED TESTING Volume IV

Co-Chairmen: A. G. H. DIETZ, *Massachusetts Institute of Technology; and* FREDERICK R. EIRICH, *Polytechnic Institute of Brooklyn.* This volume is based on the Fourth Annual Symposium on High Speed Testing, held in Boston, May 15–16, 1963, and sponsored by the Plas-Tech Equipment Corporation. It explores the latest developments in theory, instrumentation, test techniques, interpretation of test data, and application of results. An Interscience Book. *1963. Approx. 280 pages. Prob. $11.00.*

GENERAL CHEMISTRY, A PROGRAMMED REVIEW

By LUCIANA SACERDOTE, *Columbia University.* Employs the powerful new technique of programmed teaching as the basis for a thorough, comprehensive review of chemical principles and the physicochemical properties and reactions of the elements. *1963. Approx. 336 pages. $4.75.*

The Chemistry of Rhenium

K. B. Lebedev, translated by *L. Ronson* in collaboration with *A. A. Woolf*. Butterworths, London, 1962. x + 105 pp. Figs. and tables. 14 × 22 cm. $7.50.

This short volume differs from the previous monographs of Tribalat (1957) and Druce (1948) in that the main emphasis is on the occurrence, separation, and production of the element. The only chemistry considered is that related to production processes. Since the original Russian publication is based on the literature up to 1959, this volume is already slightly out of date. Although naturally the Russian practice is emphasized, the foreign literature is adequately covered. Information on the prediction, and discovery of rhenium are very briefly covered in Chapter I. Chapter II contains considerable detail on the properties of rhenium metal, its alloys, oxides, and perrhenates; while the uses of rhenium are discussed in Chapter III. Production data are also included in Chapter III, although the data for Russia are curiously missing. The geochemistry of rhenium and the recovery of rhenium from molybdenum sources are discussed in Chapter IV. The methods used for the extraction of rhenium compounds, complete with flow sheets, are discussed in Chapter V. Chapter VI is devoted to methods of reduction to the element. Chapter VII briefly deals with the analytical chemistry. Although the reviewer cannot vouch for the accuracy of the translation, the English version certainly is readable. The average chemist probably will not be interested in purchasing this book unless he is specifically interested in this element.

EDWIN M. LARSEN
University of Wisconsin
Madison

Phthalocyanine Compounds

Frank H. Moser and *Arthur L. Thomas*, Standard Ultramarine and Color Co., Huntington, West Virginia. ACS Monograph No. 157. Reinhold Publishing Corp., New York, 1963. xiii + 365 pp. Figs. and tables. 16 × 23.5 cm. $18.

The only chromophore discovered to date in the 20th century is "Phthalocyanine." The name, coined by R. P. Linstead, means "rock oil dark blue." The authors have performed a major service by condensing its literature, to mid-April, 1962, into book form. Long lists of references follow each chapter.

NEW AND FORTHCOMING TEXTS FROM McGRAW-HILL

ORGANIC CHEMISTRY
Second Edition

By CORWIN HANSCH, Pomona College, and GEORGE HELMKAMP, University of California at Riverside. 320 pages, $3.95.

As in the first edition, the text presents a very concise outline of organic chemistry, but its primary purpose is to provide a large number of problems and specific help in learning to solve these problems. Each chapter begins with simple questions and answers which lead gradually to more difficult problems. A new chapter on molecular orbitals has been included, and the mechanisms of organic reactions are emphasized more than in the first edition.

RETRIEVAL GUIDE TO THERMOPHYSICAL PROPERTIES RESEARCH LITERATURE, Vol. 2 (Books 1,2,3)

Edited By Y. S. TOULOUKIAN, Director, Thermophysical Properties Research Center. Off press.

This second volume extends the work of the Center to provide an additional 10,000 references to the seven thermophysical properties covered in Volume I. Book 1 is a classified Director of Substances, and also contains several indexes and guides which greatly enhance its usefulness. Book 2 contains classified code entries for the seven properties. Part A of book 3 provides bibliographic citations covering journals as well as university dissertations and government and industrial reports. Part B contains an index of contributing authors.

ORGANIC CHEMISTRY
Second Edition

By DONALD J. CRAM, University of California, Los Angeles; and GEORGE S. HAMMOND, California Institute of Technology. 768 pages, $10.75.

This excellent revision continues to stress the principles that govern organic reactions rather than relying on mere description. The first part acquaints the reader with structural concepts, the middle part with organic reactions taken up class by class, and the last part includes a more conventional treatment of special topics. The new edition has been expanded and presented in a more desirable sequence. In addition, the book has been printed in two colors.

INTRODUCTION TO BIOPHYSICAL CHEMISTRY

By R. BRUCE MARTIN, University of Virginia. Available in January, 1964.

This new text covers the application of fundamental principles to small molecules of biological significance, including the methods for characterizing biopolymers and a study of their properties and interrelationships. Among the topics: the thermodynamic basis of biological reactions, a systematic presentation of acid-base equilibria, and the properties, functions, and interrelationships of biologically important macromolecules, proteins, and nucleic acids.

GROUP THEORY AND QUANTUM MECHANICS

By MICHAEL TINKHAM, University of California, Berkeley. International Series in Pure and Applied Physics. Available in January, 1964.

This new volume presents the elements of group theory most pertinent to physical applications and provides a brief but systematic analysis of the quantum mechanics of atoms, molecules, and solids, emphasizing the use of group theoretical techniques. Features: a lucid presentation of the calculation of energy levels and selection rules. . .a treatment of the magnetic groups with illustrative applications to real magnetic groups. . .exercises follow each chapter.

CRYSTALLIZATION OF POLYMERS

By LEO MANDELKERN, Florida State University. McGraw-Hill Series in Advanced Chemistry. 320 pages, $11.00.

This definitive work reviews and examines critically the state of knowledge of the phenomena of crystallization of polymers. All classes and types of macromolecules are considered from the standpoint of the basic disciplines of chemistry and physics. Emphasis is on fundamental scientific concepts.

CHEMISTRY, Second Edition

By M. J. SIENKO and R. A. PLANE, Cornell University. 623 pages $7.95.

A careful revision and improvement of this excellent textbook in college chemistry. Neither the character or the scope of the book has been changed, but the authors, with a multitude of reviewers, have reexamined and strengthened the first edition. The changes result in increased depth and lucidity rather than increased size. The aim of the book, as before, is to present an introductory course which is quantitative, up to date, and of sufficient rigor to prepare the student for further work in the field.

Always Specify PIONEER Labware For Finest Quality

Made of Corrosion-Free Polyethylene

Extra Tubing Connectors Available

FILTER PUMP

Operates on water pressure from 11 lbs. up All-polyethylene. Integral check valve not affected by fumes or corrosive filtrate. Takes up to 3/8″ tubing—connects and disconnects instantly. Has 3/8″ IP male thread faucet connection.

$17.40 Per Dozen

BUCHNER FUNNELS

Sturdy two-piece construction. Easily cleaned and unbreakable. Light in weight thus not top-heavy.

Four convenient sizes

BU-43 BU-55 BU-70 BU-90

Priced from $1.75 each in case (12) lots.

From $18.00/case of 72(.25 ea.)

QD CONNECTORS

Two Sizes

A quick disconnect flexible tubing connector. Designed particularly for vacuum applications. Also useful for connecting water lines, manometers, etc. Light in weight and may be used safely in apparatus set ups.

REAGENT DISPENSER

The Safe Way to Handle Acids. Screws on any standard 5 pt. acid bottle and regular gallon or 1/2 gallon jugs. One hand operation delivers reagent at about 1000 ml. per minute. Slight pressure on relief valve stops flow instantly. Priced 3 for $11.25.

Send for catalog of complete line of unbreakable polyethylene labware —sold through leading supply houses.

PIONEER PLASTICS, INC.

ENGINEERED PLASTIC LABWARE PRODUCTS

DEPT. J BOX 8066 JACKSONVILLE 11, FLORIDA

The first two chapters give a brief account of the accidental discovery of this useful pigment, and detail the determination of the structure of the phthalocyanines and their relation to chlorophyll and hemin. The physical properties of phthalocyanines are described in terms of X-ray crystal data; the importance of, and the differences between, the alpha, beta, and gamma forms of the pigment are explained. Discussed among other aspects are the optical, electrical, and photochemical behavior. Chapters 3 and 4 review the numerous ways of preparing phthalocyanine and its derivatives on laboratory and factory scales. Finishing processes needed for maximum color development are described.

Dyes form the subject of Chapter 5. Attachment of various substituents on the phthalocyanine ring make the products soluble in either organic or aqueous solvents. Cobalt phthalocyanine is the preferred raw material for preparing vat dyes in commercial use. Colors fall into the blue-green end of the spectrum.

Commercial applications (Chapter 6) of phthalocyanines divide into two categories. Colorant uses cover paint, plastics, printing inks, rubber, and textiles. Non-colorant uses list such items as catalysts, gelation of oils to greases, analytical chemistry, medical and biological, electrical, and nuclear reactor systems. Here the pigment protects lubricants against high energy neutron irradiation.

The last two chapters concern modifications made in the fundamental porphyrin nucleus. Three types of phthalocyanine polymers are reviewed. The first has simple C–C bonds of the diphenyl type linking adjacent phthalo rings. The second type has a methylene, or equivalent, unit connecting the phthalo rings; in the last, adjacent units share phenylene rings in common.

Appendixes (3) provide a good general bibliography to the phthalocyanines; a series of testing and analytical procedures; and a portion of the *Colour Index* giving C. I. name, number, trade name, and manufacturer of various pigments. Author and subject indexes complete the book.

Phthalocyanines have esthetic values, but nowhere in the book will one find color plates to illustrate the raw and the finished pigment; the effect of chemical modification, or the influence of crystal form and particle size on the tinctorial values. In view of the excellent color printing available today, the absence of color plates is lamentable. On the chemical side the book is nearly silent concerning mechanisms by which phthalocyanine formation takes place. No mention is made of reaction kinetics or order.

A short glossary of terms peculiar to the dye, pigment, and textile industries would help a novice in this field. The writers provide authenticity for their story by numerous direct quotations from the sources in English, French, and German. Since patents form a large portion of the

IMPORTANT NEW TITLES FROM MACMILLAN

Forthcoming:

PRINCIPLES OF CHEMISTRY, Seventh Edition

By **Joel H. Hildebrand,** Professor Emeritus of Chemistry, and **Richard E. Powell,** University of California (Berkeley)

Professors Hildebrand and Powell present the principles of chemistry largely in "genetic" order, using the physical-chemical approach. The new edition has been completely rewritten, new teaching techniques have been employed, and the material has been arranged for greater efficiency. Each new principle is supported, as it is introduced, by illustrative data, usually in tabular form. Many advanced or specialized topics have been included as optional work for exceptional students. The language and methods of thermochemistry and thermodynamics have been used throughout, with emphasis on general concepts and applications rather than on formalism.

Spring 1964, Approximately 600 pages, probably $7.50

A LABORATORY COURSE IN GENERAL CHEMISTRY

by **Wendell M. Latimer,** late Professor of Chemistry, and **Richard E. Powell,** University of California (Berkeley)

This paperbound manual has been class-tested for appropriateness and safety. It has been extensively revised in this edition, and increased emphasis has been placed on chemical reactions and equilibria. Although designed for use with *General Chemistry*, the book may be used with a number of other introductory texts.

Spring 1964, Approximately 140 pages, probably $3.95

FREE RADICAL REACTIONS IN PREPARATIVE ORGANIC CHEMISTRY

By **George Sosnovsky,** Illinois Institute of Technology

This is the first manual to discuss and evaluate the existing literature on the chemistry of free radical reactions from a preparative viewpoint. It gives a thorough account of reactions in solution, thus providing a valuable tool for many syntheses that are not accessible by classical methods. The work is conveniently divided into chapters and sections according to general classes and specific types of compounds. It includes many valuable tables and there is a detailed bibliography at the end of each chapter.

Spring 1964, Approximately 500 pages, probably $16.00

International Series of Monographs on Analytical Chemistry, Volume 7:

GRAVIMETRIC ANALYSIS, Volume 1

By **Laszlo Erdey,** Technical University of Budapest

The author discusses the advantages of gravimetric micromethods of analysis over qualitative and quantitative analysis. Special attention is given to the results obtained by gravimetric and the much faster titrimetric methods. The text contains many examples and a particularly helpful bibliography.

A Pergamon Press Book — *342 pages, $7.50*

THE TECHNOLOGY OF POLYESTER FIBRES

By **B. V. Petukhov**

This manual outlines the theoretical and experimental fundamentals of the production of polyester fibre from polyethylene terephthalate, as well as giving the properties of the fibre and its principal applications.

A Pergamon Press Book — *104 pages, $4.50*

Progress in the Chemistry of Fats and Other Lipids, Volume 7, Part 2:

GAS CHROMATOGRAPHY OF LIPIDS

By **E. C. Horning, A. Karmen,** and **G. G. Sweeley,** National Heart Institute, Bethesda, Maryland

Current applications involving saturated and unsaturated long-chain fatty acids are covered in this study. It also treats newly-developed methods that are suitable for polyfunctional compounds and for steroids, giving summaries of original work from the authors' laboratories. The book will be of special interest to biologists and biochemists.

A Pergamon Press Book — *86 pages, $5.00*

Recently Published:

ORGANIC CHEMISTRY

By **F. G. Bordwell,** Northwestern University

The combination of a consistently experimental approach with thoroughness and economy of presentation makes this an excellent introduction to the theories and practices of organic chemistry. An organization on the dual basis of structure and mechanism, plus the interweaving and sampling of less fundamental material, gives the book unusual depth of coverage. At the same time, a cumulative expansion of basic principles reinforces the student's understanding of the properties of important structural classes of organic compounds and gives him an increasingly profound insight into each topic. The steps in experimental determination of organic structures are clearly defined, and full instruction in the experimental use of spectra is provided. *1962, 933 pages, $11.00*

LABORATORY PRACTICE OF ORGANIC CHEMISTRY, Fourth Edition

By **G. Ross Robertson** and **Thomas Jacobs,** University of California at Los Angeles

The distinctive feature of this manual is its extensive treatment of the principles underlying laboratory manipulations. The new edition features an expanded and modernized discussion of general laboratory technique, plus additions, deletions, and improvements in all experiments. There are new examples of elementary qualitative analysis, and the authors have expanded the selection of "Special Experiments," designed for students who have acquired a firm grasp of the fundamentals.

1962, 391 pages, $5.75

SEMI-MICRO LABORATORY EXERCISES IN GENERAL CHEMISTRY, Third Edition

By **J. Austin Burrows** and **Paul Arthur,** both of the Oklahoma State University of Agriculture and Applied Science, and **Otto M. Smith,** Kansas State Teachers College

The fifty-four experiments in this newly-revised manual range from relatively simple basic procedures to problems that will stimulate the most eager mind. Nine unusual new experiments cover topics such as radioactivity and its applications, paper chromatography, ion-exchange rates, sublimations, and steam distillation. Fourteen of the experiments are quantitative in nature, some dealing with an unknown, and there are eight qualitative experiments, covering both anions and cations.

1962, 320 pages, paper, $4.25

SCHUCO

SEMI-MICRO SETS

for • EDUCATION
• RESEARCH
• INDUSTRY

• Complete, Compact, Ready for Use
• Framework and Supports Included
• Low Cost and Minimum Breakage
• Cabinets Contain all Components

The SCHUCO range of SEMI-MICRO apparatus provides simple, compact sets ideal for school use to sets giving over twenty different assemblies for post-graduates and the research worker. Unique features are the special portable cabinets complete with fittings, including acid resistant working base, rigid metal framework and micro burner. The clamp/bosshead attachments which support the glass apparatus eliminate traditional bossheads and clamps making the whole outfit a composite "ready-to use" apparatus needing no extras.

*Set No. E. S. 7: Consisting of 16 components with ground joints. Complete with cabinet and framework... $69.00

*Set No. E. S. 8: Consisting of 21 components with ground joints. Complete with cabinet and framework... $84.00

*Set No. E. S. 11: Consisting of 6 components which can be used to supplement either set E.S. 7 or E.S. 8. Can also be used as simple introductory set. Complete without case or framework. $13.00

*Quantity Discounts: 1-11 sets net, 12-23 sets 10%, 24-49 sets 15%, 50 or more sets 20%. Sets E.S.7 and E.S. 8 only may be assorted to earn quantity discounts.

Available from SCHUCO or your Lab Dealer.

Farben in Kultur und Leben

Hans Kramer and *Otto Matschoss.* Ernst Battenberg Verlag, Stuttgart, 1963. 276 pp. Figures. 25 × 35 cm. 138 DM ($33.50).

In August, 1863, Friedrich Bayer began the manufacture of aniline at Barmen. This modest undertaking has now grown into the colossus known as Farbenfabriken Bayer AG, which in 1962 offered 8500 items of which 3500 were dyes and related products. The centenary of this corporation will be appropriately celebrated and the volume under review here was issued in honor of this occasion. It fittingly bears the title "Colors in Culture and Life," and presents an encyclopedic treatment of this vast subject. The level of the discussions is nontechnical but adult; the aim has been to entertain and inform the educated general public.

The text has been divided into four main topics, each with competent authors. The first three divisions are entitled: Nature and Color; The Magic of Color; Man and Color, which in turn are divided into sections each with a separate heading. In this way practically the entire field has been covered in various degrees of extension and depth. Typical topics are: the physics of color, the perception of color, the colors used at various periods of human history, the cave paintings, color in the animal, vegetable, and mineral kingdoms, the psychological aspects of color, the theory of colors and their combination, mosaics, cermics, glasses, tapestries, the history of painting, the symbolism of color, etc. In short, there are few facets of the subject that have not been at least mentioned.

Chemists will be particularly interested in the fourth main division: Coloring Matters Through the Centuries. The author is Rudolf Sachtleben, formerly curator of the chemical section of the Deutsches Museum in Munich and an experienced essayist in the field of the history of materials. He here has given an expert account of colors since the glacial periods, stressing the mineral, animal and vegetable materials used by artists and dyers through these many centuries. There are no equations or structural formulas but the essential information is nevertheless all there. This portion of the book in itself will commend the volume to teachers and students.

The excellence of the text is fully matched by the beauty and appropriateness of the 99 illustrations. They are all in

two new chemistry texts

ELECTRONIC SPECTRA AND QUANTUM CHEMISTRY
by C. Sandorfy, University of Montreal

An easy-to-read introduction to research in electronic spectra. Emphasizes "working knowledge." Presentation stresses the larger molecules. Describes the approximate wave mechanical methods that allow theoretical computation of frequencies and intensities of spectral bands. *Feb. 1964, approx. 352 pp., Text price $10.00.*

COLLEGE CHEMISTRY 3RD EDITION
by Paul R. Frey, Colorado State University

Based on a concept-building approach, the book introduces one new idea in each section, making the text flexible. Emphasizes the quantitative aspects of chemistry. Approach to atomic structure stresses probability of electron position, ionization potentials, electronegatives, and bond energies. *April 1964, approx. 700 pp., Text price $8.50.*

and one already tested in the classroom

SYNTHETIC INORGANIC CHEMISTRY
by William L. Jolly, University of California at Berkeley

A theoretical and operational text to accompany courses in preparative inorganic chemistry. More than just a "cookbook" of formulas or a book on techniques, it is a text that shows how the synthetic inorganic chemist thinks. *1961, 196 pp., Text price $6.95.*

New and Recent Quality Texts in Chemistry

Coming in 1964

GENERAL CHEMISTRY: A PHYSICAL APPROACH by William F. Sheehan, University of Santa Clara

By utilizing elementary concepts of Physical Chemistry, this text presents subjects of theoretical importance to beginning students at the freshman level. Emphasis lies mainly on structural chemistry together with certain simple aspects of valence theory, quantum theory, thermodynamics, and kinetics. est. 592 pp. List $8.75 tentative.

1963 Publications

PRINCIPLES OF CHEMISTRY, SECOND EDITION by Donald C. Gregg, University of Vermont

With the inclusion of more descriptive chemistry, the second edition continues to emphasize the meanings, origins, and applications of major chemical concepts. Many important concepts have been added, such as quantum theory, hybrid bonds, entropy, and free energy. 716 pp. List $8.50.

ORGANIC CHEMISTRY: PRINCIPLES AND APPLICATIONS by Siegfried Nussenbaum, Sacramento State College

A new text utilizing a unique approach to organic chemistry. The student achieves perspective through a balanced presentation of modern theory and classical and descriptive organic chemistry. Through the use of the optional sections contained in this text, the instructor is allowed considerable flexibility by choosing appropriate special topics according to the interests and requirements of the class. 625 pp. List $8.95.

Other Prominent Chemistry Texts

INTRODUCTION TO QUALITATIVE ANALYSIS by Durward C. Layde, University of Wisconsin—Milwaukee

This thoroughly tested text introduces the student to equilibrium and solution chemistry, along with the reactions of the familiar cations and anions. It is comprised of three sections: theory, groups of metals, and experiments. 350 pp. List $6.50.

EXPERIMENTS IN QUALITATIVE ANALYSIS by Durward C. Layde, University of Wisconsin—Milwaukee

An abridged edition of the author's *Introduction to Qualitative Analysis*, this book retains the same class-tested experiments. It is designed for a general chemistry course in which qualitative analysis is developed in the laboratory during the second semester. 239 pp. Paperbound. List $3.75.

COLLEGE CHEMISTRY by Donald C. Gregg, University of Vermont

An introductory text examining the major chemical principles and a feasible number of elements, compounds, and their chemical properties. It includes emphasis on the modern conceptions of atomic weights, chemical symbols and equations, atomic structure, and the physical character of covalent and ionic compounds. 593 pp. List $7.95.

EXPERIMENTS IN GENERAL CHEMISTRY by Russell S. Drago and Theodore L. Brown, University of Illinois

A laboratory manual containing thought-provoking experiments designed to accompany any general chemistry text. The exercises at the end of each experiment test the student's understanding of his accomplishments in the laboratory. 236 pp. Paperbound. List $4.95.

ORGANIC CHEMISTRY by Robert T. Morrison and Robert N. Boyd, New York University

Considered the finest modern chemistry text in the organic field, this best-selling text stresses the understanding of chemical principles by showing the dependence of properties upon structure. Fundamental concepts such as orbital theory, stereochemistry, resonance, inductive effects, and modern concepts of acids and bases are introduced early in the book and applied throughout. 948 pp. List $11.50.

Cincinnati, Ohio

Some Cosmochemical Problems: Notes on the Thirty-Seventh Annual Priestley Lectures

Harold C. Urey, University of California, San Diego. Pennsylvania State University, University Park, 1963. x + 181 pp. Figs. and tables. 21.5 × 27.5 cm. Paperbound. $3.25.

This paperbound book consists of notes prepared from tape recordings and slides used by Professor Urey in the presentation of the Thirty-Seventh Annual Priestley Lecture Series at Pennsylvania State University. The notes, as compiled by an editorial committee, were submitted to Professor Urey for his comments and corrections.

The volume consists of notes from five lectures entitled: Chapter I, The Moon; Chapter II, The Abundance of the Elements; Chapter III, The Origin of the Solar System-I; Chapter IV, The Origin of the Solar System-II; and Chapter V, The Origin of the Elements. Questions from the audience and Dr. Urey's answers are included. As stated by Dr. Urey, most of the material covered in the lectures has been published in review articles he has written in "Space Science," John Wiley and Sons, 1963 and "The Moon," Academic Press, 1962. The principle merit of this volume of lecture notes is that it is addressed to non-specialists in cosmochemistry. Dr. Urey takes care to trace the historical evolution of the ideas and theories he discusses. This unfolding process leads to a far greater appreciation by the reader of the serious problems in this field, than if only current theories were discussed.

As might be expected in a book derived from transcriptions of lecture notes, there are some weaknesses. Proofreading of the manuscript was poorly done and typographical errors are common. Spelling of names in the references was quite variable with, for example, Suess and Seuss being used about equally. The material is not as well organized as it would be in a manuscript specially written for publication. For example, terms such as "chondrites" are used in the text many pages before they are finally defined. In several cases extensive tables of data are presented, whereas the text will only briefly touch on their significance. References to original sources of the data presented are quite deficient.

In summary, the editorial committee has succeeded in capturing the inimitable style of Dr. Urey speaking about a field to which he has made significant contributions and in which he is vitally interested. The book can be read by the non-specialist profitably and with enjoyment. While certainly not a text or a source book for the specialist, the book could be used effectively by college teachers and advanced students in chemistry, and other physical sciences for supplemental reading in a new and fascinating field of chemistry. Its modest cost should allow its inclusion into even the smallest libraries.

WILLIAM D. EHMANN
University of Kentucky
Lexington

NOBLE-GAS COMPOUNDS

Edited by Herbert H. Hyman

This volume reports the research that toppled a chemical theory accepted for nearly seventy years—the theory that no member of the periodic table's family of so-called inert gases formed a stable chemical compound.

The intense interest exhibited in the chemistry of xenon stems from the important role that the inert gases have played in the development and teaching of theories of chemical combination. The search for an adequate theoretical basis for the experimental results has raised fundamental questions and suggested answers with the broadest potential significance.

The first true compound of a hitherto inert gas was prepared at the University of British Columbia and reported in June, 1962. The announcement of the synthesis of xenon tetrafluoride at Argonne National Laboratory in September, 1962, initiated research in an ever-increasing number of laboratories and stimulated much serious theoretical speculation. The papers gathered here were presented at the first conference held on the subject and represent a complete summary of research in this field.

G. P. PUTNAM'S SONS

Books for Nurses since 1878

Three Outstanding Textbooks by ARMAND J. COURCHAINE

NEW! BASIC HUMAN BIOCHEMISTRY

The fundamental principles of physical, biophysical, organic and biological chemistry are presented in this textbook in a clarifying direct-approach method. While it is designed primarily for students with little background in the study of chemistry, BASIC HUMAN BIOCHEMISTRY is neither oversimplified nor limited in the scope of its subject matter. Fully illustrated. Complete index.

484 pages September 1963 $7.00

CHEMISTRY VISUALIZED AND APPLIED

A thoroughly up-to-date text which demonstrates that chemistry is not the difficult science that many students believe it to be. The relationship between chemistry and physics is described clearly; correlations are shown wherever possible relating chemistry to medicine, physiology, pathology, pharmacology, microbiology, nutrition, nursing and dentistry, as well as to certain industrial and everyday functions. CHEMISTRY VISUALIZED AND APPLIED clarifies the formula and the equation as practical and convenient tools. It is fully illustrated with schematic drawings and photographs. Complete appendix and index.

687 pages Second edition 1957 $5.50

SIMPLIFIED CHEMISTRY EXPERIMENTS

The fundamentals of inorganic, organic and physiological chemistry are covered by this laboratory manual, with emphasis on economy of time, effort and materials. Using carefully developed questions, the author requires the student to arrange and interpret the material exercising considerable independent thought. Included in this manual is a suggested outline for a 60-hour course, although it contains sufficient material for 120 laboratory hours. Each exercise is preceded by a list of materials needed and directions for the preparations of reagents. SIMPLIFIED CHEMISTRY EXPERIMENTS can be used with any standard text.

235 pages; spiral-bound 1950 $2.50

Complimentary examination copies available to teachers.

their respective fields. In each chapter the author presents the past accomplishments, current methods, and future trends in the subject under discussion. These men have done an excellent job capsuling the literature in these special areas for the reader.

The contents are as follows: Laminar Flow of Single-Phase Newtonian Systems by Professor Acrivos; Turbulent Flow of Newtonian Systems by C. A. Sleicher; Liquid-Liquid Extraction by R. B. Olney and R. S. Miller; Non-Newtonianism in Thin Liquids: Molecular and Physical Aspects by E. W. Merrill; Viscoelastic Phenomena in Thick Liquids: Phenomenological Analysis by A. G. Frederickson; Solid-Fluid Systems by F. A. Zenz; Flow of Fluids Through Porous Materials by R. E. Collins; Gas-Liquid Flow in Conduits by A. E. Dukler and M. Wicks, III; Absorption and Distillation by J. E. Vivian and C. J. King; Chromatographic Separations by R. F. Baddour and J. R. Valbert; Process Dynamics and Control by L. Lapidus and D. E. Lamb.

The only critical comment from this reviewer is the type used in the printing of the book. Apparently, the type is too bold and after several hours of perusal, the efficiency of reading decreases greatly as compared to the type used in most chemical engineering books. In many cases the figures are difficult to read because of the small size. These are minor items but should be taken care of in the following editions.

A copy of this book should be on the book shelf of each professor and each industrial worker specializing in one of the areas covered by the book.

JOHN J. MCKETTA
University of Texas
Austin

The Organic Constituents of Higher Plants: Their Chemistry and Interrelationships

Trevor Robinson, University of Massachusetts, Amherst. Burgess Publishing Co., Minneapolis, Minn., 1963. iii + 306 pp. Figs. and tables. 22 × 28.5cm. $6.75.

As biological research has become more and more a matter of chemical investigation, the need of the biologist for knowledge on the chemistry of natural products from a biological rather than chemical outlook has become more urgent. The purpose of Professor Trevor Robinson's book is to provide botanists with a survey of the types of organic compounds that occur in higher plants and their interrelationships without the burden of information of interest only to the chemist. Although the brief chapter titles do not indicate it, the compounds are grouped according to their mode of biogenesis rather than strictly by chemical structure; this novel and useful classification is an outstanding characteristic of the book. For each group are given the structures and sources of representative and unusual examples, chemical and physical properties, and function, techniques of isolation and characterization, and literature references to comprehensive reviews and specific papers. The danger of mistaking artifacts produced during isolation for naturally occurring compounds is well illustrated. For well-known classes such as carbohydrates and amino acids, emphasis is placed on lesser known examples, but for alkaloids, the importance and widespread occurrence are not adequately conveyed. Structure proofs and syntheses, which usually occupy much of the literature on natural products, are not discussed, since they are not of concern to the biologist. In almost all instances it will be necessary to consult the original literature or reviews for the details on experimental procedures or for inclusive lists of compounds of a given group; the well-selected references make this no problem at all.

The survey of structures produced by higher plants is quite extensive; the only omissions noted by this reviewer are the fluorine-containing fatty acids present as toxic constituents of several plants and 2-aminoethylphosphonic acid, the only known occurrence of the C—P bond. Readers desiring to acquire a knowledge of the types of compounds that occur naturally should bear in mind that this is not a survey of all natural products found in plants and that a very large part of the recent work in the field has been concerned with microorganisms, from which much more unusual types of structures have been obtained. (The latter are cataloged in "The Pfizer Handbook of Microbial Metabolites.")

The very few typographical errors in the text are trivial. A book of this type requires a large number of structural formulas, and the abundance of such formulas is another excellent feature. Although most of the formulas have been reproduced directly from the author's drawings, there are numerous errors, perhaps more than average for such books. A large number of the formulas were checked; errors were noted in the structures given for salicin, gentisic acid, collinin, tasmanone, α-kosin, khellin, eucarvone, lanceol, hecogenin, solanidine, fukugetin, thiamine, folic acid, and folinic acid. Although such errors seriously detract from an otherwise well-executed book and will be a thorn to workers, they should not bother the general reader. The avoidance of unnecessary chemical jargon and conventions is desirable in a book intended primarily for biologists, but the use of double-headed arrows for reversible reactions (pp. 31, 32) is objectionable to chemists; the nonconventional representation of porphyrin rings is confusing; and the expression, "methylation increases the redness," (p. 186)—bathochromic shift or hyperchromic effect?—is ambiguous.

This book can be highly recommended not only to botanists but to chemists and all workers in the field of natural products. Teachers of organic chemistry would profit by browsing through this book to become aware of the pattern of carbon compounds in nature, and the book should be placed near the top of the bibliography for courses in the chemistry of natural products.

Determination of Saponification Equivalents of Phenolic Esters

See TOBEY, S. W., *et al.*, *J. Chem. Educ.*, 38, 611 (1961).

In the identification of compounds many different properties can be used such as molecular weight, color, infrared absorption characteristics, behavior in various chemical environments, and others. One identifying feature, often used for esters, is the weight (in grams) of ester per equivalent of base needed to saponify the ester. This ratio is called the "saponification equivalent." Phenolic esters often do not yield reproducible saponification equivalents when the procedures described in various reference works are used. The authors have developed a procedure which does give reliable results with phenolic or any other esters.

Questions:

The authors state that they are not sure why the older procedures for the determination of the saponification equivalent of an ester often fail with phenolic esters, though they do suggest a few possible reasons. Can you establish that one or more of the reasons they suggest are valid, or, can your determine some other explanation?

The authors indicate that phenolphthalein cannot be used as an indicator in the back titration step of their procedure since phenol is itself acidic enough to react appreciably with the base before the phenolphthalein has changed color. Therefore, they recommend the use of another indicator. Phenolphthalein could be used, however, if before the back titration the phenol were tied up chemically in some way so that its acidic character would not be evident. Can you suggest a practical scheme for accomplishing this result?

When determining the saponification equivalent of phenolic esters which have a nitro substituent on the aromatic nucleus, thymolphthalein should be used as the indicator in the back titration step because most substituted phenols have *p*K values less than 9.2. Can you find any phenolic esters with a nitro substituent on the aromatic nucleus for which thymophthalein is not required as the indicator in the back titration step? Or, can you find any other aromatic esters, in addition to those mentioned by the authors, which are not nitro derivatives of phenol, for which thymolphthalein is required as an indicator in the back titration step?

Can you succeed where the authors failed, and develop a mixed indicator which would be suitable for both types of phenolic esters, those with phenol derivative moieties with *p*K values above, and below, 9.2?

The saponification equivalents of carboxylic acid esters of polyhydroxyl aromatic compounds and of esters of *p*-hydroxybenzoic acid and *p*-hydroxycinnamic acid cannot be determined by the procedures described. Can you devise a suitable procedure for one or more of these classes of esters?

NOTES: The investigations suggested by the questions here are recommended for the student who has a strong interest in, and comprehension of, organic chemistry and analytical chemistry.

The use of tris(hydroxymethyl)aminomethane as a primary standard, though recommended, is not mandatory. See THIS JOURNAL, 36, 297 (1959). Similarly, apparatus with standard taper joints will facilitate the experimental work but is not essential.

A Biochemistry Laboratory Experiment

See SCHER, I., *et al.*, *J. Chem. Educ.*, 38, 632 (1961).

When an electrical discharge is passed through a gas or mixtures of gases, new products are often formed as a result of the action of the electrical discharge. It has been postulated that prior to the existence of life on the earth, an analogous natural process produced the essential components for living forms, which then followed as a consequence. The authors of this article report that they found evidence for the formation of some amino acids and other products when an electrical discharge was passed for several days through a mixture of ammonia, water vapor, and ordinary burner gas.

Question:

Construct an apparatus similar to that described in the article and fill it with a suitable gas or gas mixture. Pass an electrical discharge (a spark coil from a "Model T" Ford—these are still available at reasonable cost—can be used instead of the induction coil recommended) through the gas for a suitable period of time, and identify as many of the products formed as possible. Account for the formation of these products and test your suggestions by further laboratory work.

NOTE: Since explosive mixtures of gas may inadvertently be used initially or might be formed during the course of a run, be sure to use safety shields and to wear safety goggles when conducting this investigation.

A Constant Current Source for Student Use

See MANN, C. K., AND CHAMPEAUX, V. C., *J. Chem. Educ.*, 38, 519 (1961).

For many modern studies in quantitative analytical chemistry a source of constant current is necessary. Most of these studies comprise investigations in one of these fields: coulometric titration at constant current, potentiometric titration at constant current, chronopotentiometry, and current scanning potentiometry. Of these the first is probably the simplest for a beginner to study.

In the article, the construction of an inexpensive transistorized constant current source is described. No specific suggestions are made for its use in an experimental investigation.

Question:

Construct the constant current source described and use it to help solve a problem posed in another chemical project in this series. It is suggested that the first problem you select involve a titration which you can adapt to a constant current coulometric titration.

REMOVAL OF HARDNESS AND DEIONIZATION OF WATER BY THE ION EXCHANGE METHOD

A Chem Ed TESTED DEMONSTRATION

Submitted by: A. W. Sangster, University College of the West Indies, Jamaica
Checked by: Marcus Kraus and James Ramer, Tenth Chemistry Institute, Montana State College

Materials: Cation Exch. Resin, Amberlite IR-120 (Col. A); Anion Exch, Resin, Amberlite IRA-400 (Col. B); hard water, 1 liter of 2% $CaCl_2$ soln; 500 ml of 10% NaCl soln; 250 ml of 1 *M* HCl; 250 ml of 1 *M* NaOH; 0.5 *M* $(NH_4)_2C_2O_4$ soln for Ca^{++} test; 0.25 *M* $AgNO_3$ soln for Cl^- test.

PART I—Removal of Hardness (Ca^{++})

Preparation of column A: Pass through 250 ml NaCl soln slowly until effluent positive for Na^+ with Nichrome wire. Wash column thoroughly with 500 ml distilled water.

Test: Add 4 drops methyl orange to 250 ml hard water. Pass through column. Test pink effluent for absence of Ca^{++}. Demonstrate removal of Ca^{++} from column A by passing through 200 ml NaCl soln. Test for Ca^{++}.

PART II—Deionization (Ca^{++} and Cl^-)

Preparation Column A	*Preparation Column B*
Pass through HCl soln until negative for Na^+. Test with Nichrome wire. Wash until effluent negative for Cl^-.	Pass through NaOH soln until positive for alkali (litmus). Wash with 500 ml distilled water.

Test: Add 5 drops methyl orange to 300 ml $CaCl_2$ soln. Pass through column A. Then pass pink effluent through column B. Test for absence of Ca^{++} and Cl^-.

Note: Respective column must be thoroughly washed with HCl and NaOH before test.

PART III

Removal of Ca^{++}:
(cation exchange): $2[RSO_3^-Na^+] + Ca^{++} \rightleftharpoons [(RSO_3^-)_2Ca^{++}] + 2Na^+$

Deionization:
(cation exchange): $2[RSO_3^-H^+] + Ca^{++} + 2Cl^- \rightleftharpoons [(RSO_3^-)_2\,Ca^{++}] + 2H^+ + 2Cl^-$

(anion exchange): $[R'N(CH_3)_3OH^-] + H^+Cl^- \rightleftharpoons [R'\overset{+}{N}(CH_3)_3Cl^-] + H_2O$

VAPOR SHADOWGRAPHS

A Chem Ed TESTED DEMONSTRATION

Submitted by: L. Carroll King and A. D. Templer, Northwestern University, Evanston, Illinois

Checked by: John Shotwell, Detroit Public Schools, Michigan

PREPARATION

Provide an ultraviolet light, a fluorescent screen, a beaker or shallow dish containing the test liquid, and a long glass tube.

DEMONSTRATION

The fluorescent screen is placed in the ultraviolet light beam and the beaker of test liquid is placed near the screen. With the long glass tube blow across the liquid surface. The shadow of the vapor may be observed on the fluorescent screen.

REMARKS

Pyridine, benzene, and mercury absorb strongly in the ultraviolet; their vapor shadows are easily observed. The vapor shadows of acetone, mesityl oxide, anethol, and anisaldehyde can be seen but not so easily as the first three mentioned.

The ultraviolet light source should produce the shorter wavelengths and should be equipped with a filter to remove as much of the visible light as possible.

Note on Fluorescent Screens

A laundered white shirt makes a fine fluorescent screen. White paper used for letterheads is usually satisfactory. Crystalline anthracene or uranyl acetate spread evenly over a cardboard which is covered with a thin layer of glue will work very well.

TOPS Tested Overhead Projection Series

Compiled by
HUBERT N. ALYEA
Princeton University

Insistent demands for copies of the instalments already published in this series have prompted the publication of this initial reprint. It contains all the instalments published in the *Journal of Chemical Education* from January 1962 through August 1963, thus including the articles on the construction of the inexpensive overhead projector and the basic kit of simplified TOPS devices.

Because "Tops in Chemistry" will take several years for complete publication, Dr. Alyea has prepared a special section, exclusively for this booklet, which he calls, "The Top Ten Tops." This lists the ten experiments best suited for projection in each of the 24 topics in his book, "Tested Demonstrations."* By referring to this book and using the data given in "The Top Ten Tops," the teacher will be able to work out his own 240 projection experiments. Eventually these will be described in greater detail in the forthcoming instalments of the TOPS series in the *Journal of Chemical Education*.

48 pages 8½" x 11" $1.50 per copy, postpaid

*Tested Demonstrations in Chemistry—208 pp
8½" x 11" $3.50 per copy, postpaid

"...especially recommended..."

POLAROGRAPHIC METHOD OF ANALYSIS

By OTTO H. MÜLLER, *Associate Professor of Physiology, State University of New York Medical Center at Syracuse, Syracuse, N.Y.*

In this second revised and augmented edition, the author purposes "to present a simple account of polarography in a form which can be used by teachers and students in physical chemistry as well as in advanced courses in analytical chemistry." The emphasis is on principles and the scope is descriptive rather than mathematical. It begins with an excellent review of electroanalysis, showing the relation of polarography to other electro methods. A brief description of apparatus includes equipment constructible from parts readily available in many laboratories. Fundamentals of quantitative and qualitative analysis and recent developments are discussed in some detail. Chapters on applications and suggestions for practical polarography complete the book.

A particularly good feature is the inclusion of 26 experiments, and the graphs and tables of data obtained from them constitute the illustrative material of the text. These experiments could be undertaken with profit by anyone desiring an experimental indoctrination in polarography.

The book is especially recommended to students, beginners in the field, and anyone desiring a brief but comprehensive introduction of the fundamentals of polarographic measurements.

. . . resolves 0.01 ug protein . . . separates 20-30 protein fractions from human serum

One hundred times more sensitive than the starch gel technique, this powerful new method separates large molecular weight substances on 1½-inch long columns of a specially processed gel. More reproducible than either paper or starch, Disc Electrophoresis is also much faster — runs of ½ hour are typical instead of up to 12 hours. And you can actually watch the "front" move.

Twelve samples may be run at one time and results *quantitatively* evaluated with an exciting new microdensitometer which scans the gel columns directly, producing a chart record of the position and density of the various bands. Some typical protein separations have produced: *14 bands from brain extract (previously 3 by starch) / 4 sharp major hemoglobins (previously 3 blurred ones on paper) / 4 bands from frog embryo (previously 1 by starch).*

For details see your Aloe Scientific representative or write Aloe Scientific, ® Division of Brunswick, 1831 Olive Street, St. Louis 3, Mo.
